*Erasmus von Rotterdam*

## ZUSAMMENFASSUNG

Chronisch entzündliche Darmerkrankungen (CED) sind immunvermittelte Erkrankungen des Gastrointestinaltrakts, welche durch komplexe Interaktion verschiedener Faktoren wie genetische Prädisposition und Umwelteinflüsse charakterisiert sind. Die Störung der Integrität intestinaler Epithelzellen ist einer der kritischen Faktoren für die Entstehung von CED. Im Hinblick auf epitheliale Dysfunktion konnten in Epithelzellen spezifische, zelluläre Stressantworten, sogenannte „unfolded protein responses“ (UPR), des endoplasmatischen Retikulums (ER) und des Mitochondriums detektiert werden, die mit der Entstehung von CED assoziiert scheinen. Diese Signalwege werden durch Akkumulation ungefalteter Proteine im ER beziehungsweise Mitochondrium aktiviert und führen in weiterem Verlauf zur Expression von „C/EBP homologous protein“ (CHOP), einem Transkriptionsfaktor, der stark mit der Induktion von Apoptose assoziiert erscheint. Bisher konnte kein funktioneller Zusammenhang zwischen UPR-vermittelter CHOP Expression und CHOP-induzierter epithelialer Apoptose in CED gezeigt werden. In der vorliegenden Arbeit sollten die Folgen einer erhöhten CHOP Expression in einer gewebsspezifischen Auflösung untersucht werden. Hierfür wurden transgene *Chop*<sup>EC Tg/Tg</sup> Mäuse generiert, welche CHOP im Darmepithel überexprimieren.

Es konnte gezeigt werden, dass eine erhöhte Expression von CHOP die Proliferationskapazität von Dickdarmepithelzellen negativ beeinflusst. Dieser Effekt schien unabhängig von Apoptose zu sein, konnte jedoch einer durch CHOP-induzierten Verzögerung der Zellzyklus-Progression zugeordnet werden. Des Weiteren konnte festgestellt werden, dass die durch CHOP reduzierte Zellproliferation mit einer verminderten Zellmigration einherging. Obwohl *Chop*<sup>EC Tg/Tg</sup> Mäuse diesen Effekt unter normalen Bedingungen kompensieren konnten, konnte bei mechanischer Schädigung der Mukosa eine verringerte Regenerationsfähigkeit des Dickdarmepithels beobachtet werden. Darüber hinaus zeigten sich *Chop*<sup>EC Tg/Tg</sup> Mäuse anfälliger gegenüber einer Dextran Natriumsulfat (Dextran Sodium Sulphate, DSS)-induzierten Kolitis, die sich bereits in der frühen Entzündung durch verstärkte Immunzellinfiltration manifestierte und sich des Weiteren in der Regenerationsphase durch eine verzögerte Heilung der Mukosa auszeichnete.

Zusammenfassend deuten unsere Ergebnisse darauf hin, dass eine verstärkte Expression von CHOP im Darmepithel das Risiko für die Entstehung von CED erhöht. Im Hinblick auf mögliche Therapieansätze sollte beachtet werden, dass CHOP als potentielles Zielprotein nicht nur Mechanismen der Apoptose beeinflusst, sondern vielmehr die Proliferation und damit die Regenerationsfähigkeit des Epithels limitiert.

## ABSTRACT

Inflammatory bowel diseases (IBD) are immune-mediated disorders of the gastrointestinal tract that are characterized by complex interactions of different factors, including genetic predisposition and environmental impacts. The disruption of intestinal epithelial integrity is one of the crucial factors considering causative triggers of IBD. With regard to epithelial dysfunction, specific cellular stress responses of the endoplasmic reticulum (ER) and the mitochondrion, also known as unfolded protein responses (UPR), could be detected in epithelial cells that have been associated with the development of IBD. These signaling pathways are activated upon accumulation of unfolded proteins in ER and mitochondrion, respectively, which subsequently leads to the expression of C/EBP homologous protein (CHOP), a transcription factor highly associated with the induction of apoptosis. Up to now, no functional correlation between UPR-related CHOP expression and CHOP-induced epithelial apoptosis has been shown in the onset of IBD. In this study, we aimed to investigate the consequences of enhanced CHOP expression in a tissue-specific resolution. Therefore, we generated transgenic *Chop*<sup>IEC Tg/Tg</sup> mice that conditionally overexpress CHOP in intestinal epithelial cells (IECs).

It has been shown that enhanced expression of CHOP negatively affected the proliferative capacity of colonic epithelial cells. This effect was most likely independent of apoptosis, but was rather associated with a CHOP-induced delay in cell cycle progression. Furthermore, it has been demonstrated that CHOP-induced decrease in cell proliferation was correlated with reduced cell migration. Even though *Chop*<sup>IEC Tg/Tg</sup> mice were able to compensate this effect under normal conditions, transgenic mice exhibited an impaired regenerative ability of the colonic epithelial lining in response to mechanically induced mucosal tissue damage. In addition, *Chop*<sup>IEC Tg/Tg</sup> mice were more susceptible to Dextran Sodium Sulphate (DSS)-induced colitis that already became evident in early inflammation due to enhanced immune cell infiltration and was further characterized by delayed mucosal healing during recovery.

In conclusion, our data suggest that high expression of CHOP in the intestinal epithelium increases the risk of IBD. With regard to potential therapeutic approaches, it should be considered that targeting CHOP protein not only affects mechanisms of apoptosis, but rather limits the proliferative capacity and regenerative ability of intestinal epithelial lining.

## 1 Introduction

Since decades scientists dedicated their work to the examination of molecular regulation patterns that cause the development and maintenance of diseases. Much knowledge was gained from intensive studies of pathological findings, thereby translating the disease-phenotype into susceptibility loci <sup>1, 2</sup>. The decoding of the human genome opened the door for genome wide association studies (GWAS) that allow the investigation of patient cohorts for unknown genetic variants <sup>3-5</sup>. Although GWAS successfully identified novel genetic risk loci and new molecular markers for diagnostic application, the etiology of complex disorders remains elusive <sup>6, 7</sup>. It is largely unknown to which extend genetic predispositions do impact on inherited risk, as distinct environmental factors contribute to the outcome of disease-phenotypes <sup>8, 9</sup>. Therefore, studies with genetically modified animal models provide important insights into the architecture of complex mechanisms by elucidating the gene-gene and gene-environment interactions, respectively <sup>10, 11</sup>.

Complex diseases, such as chronic illness has become more prevalent in the developing world <sup>12-14</sup>. Among those, IBD have been observed with steadily rising incidence rates in North America and Western Europe strongly associated with environmental triggers resulting from modern lifestyle, such as diet, changes in enteric microbiota, smoking, and stress <sup>14-17</sup>. The understanding of how these environmental factors do implicate in inherited genetic risk will hopefully lead to new therapeutic approaches to decrease the burden of chronic diseases.

## 1.1 Inflammatory bowel diseases

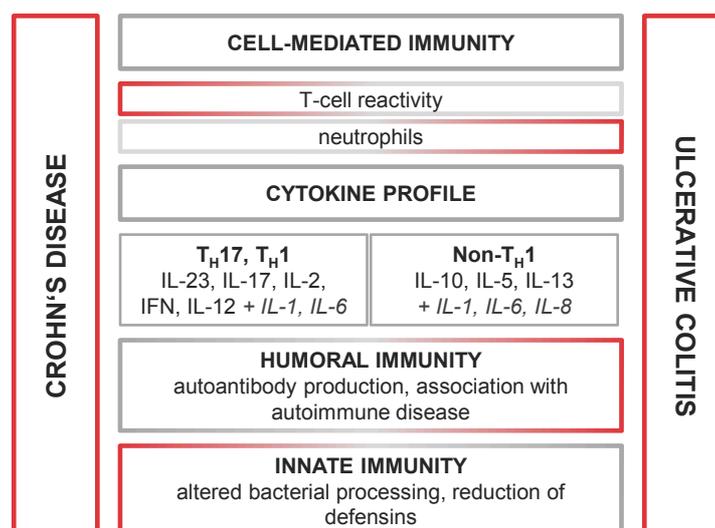

IBD including the major subtypes Crohn's disease (CD) and ulcerative colitis (UC) are chronic relapsing, immune-mediated disorders of the gastrointestinal tract that are triggered by complex interactions of genetic predisposition and environmental factors (Figure 1) <sup>18-22</sup>. The precise etiology of IBD is still unknown, but GWAS with IBD patients as well as experimental studies with human samples and genetically engineered mouse models identified distinct genetic susceptibility loci for CD and UC, respectively, that affect the maintenance of gut homeostasis <sup>23-29</sup>.

**Figure 1. Disease-phenotype of the IBD subtypes CD and UC.**

The development of IBD is triggered by complex interactions of genetic predisposition and environmental factors, thus leading to sustained immunologic dysfunction that drives the disease-phenotype of CD and UC. Chronic inflammation appears in any part of the gastrointestinal tract in CD, while it is restricted to the colon in UC. Here, colitis usually starts in the rectum and spreads proximally in severe UC.

Up to now, 163 IBD loci have been reported to influence innate and adaptive immune mechanisms relevant for intestinal barrier functions and microbial defense <sup>27, 28, 30-36</sup>. Even though there is considerable overlap in the susceptibility loci between CD and UC (110 out of 163), the two forms of IBD distinguish in the immune-mediated response to environmental factors, including commensals and pathogens (Figure 2) <sup>33, 37</sup>. Immunologic dysfunction may be further triggered by disease-specific epithelial cell responses, such as autophagy, apoptosis/necroptosis, ER stress, and oxidative stress <sup>28, 36, 38, 39</sup>. In this regard, changes in epithelial integrity, including intestinal permeability, epithelial cell proliferation or apoptosis, cellular redox equilibrium, and alterations in synthesis and secretion of antimicrobial substances are frequently associated with sustained UPR of the ER and mitochondria (mt) <sup>28, 40-42</sup>.

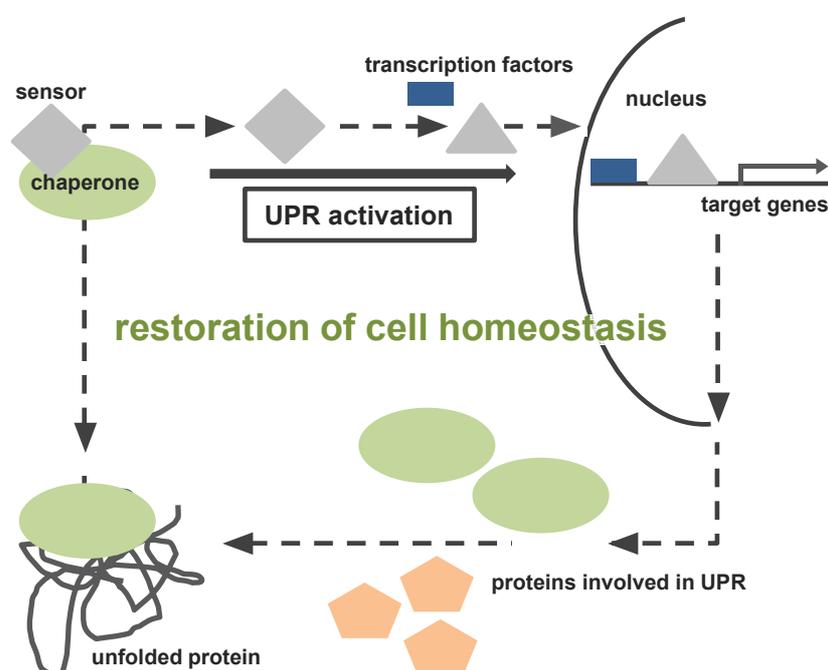

**Figure 2. Contribution of immune and inflammatory response to CD and UC.**

Cell-mediated, humoral, and innate immune responses distinctly influence the disease-phenotype of CD and UC. T-cell reactivity is enhanced in CD, but either normal or decreased in UC. Here, enhanced neutrophil infiltration could be observed. Regarding the cytokine profile, CD is characterized by  $T_H17$  response including the increased expression of interleukin (IL)-23, IL-17, IL-2, IFN, IL-12, but also other cytokines, such as IL-1 and IL-6, respectively. Cytokines, such as IL-10, IL-5, IL-13 are prominent in UC defining a non- $T_H1$  T-cell response. Humoral immune response could be observed in UC indicating an autoimmune responsiveness. Disturbances of innate immune mechanisms have been implicated in CD showing an altered processing of intracellular bacteria as well as decreased synthesis of defensins.

## 1.2 Unfolded protein responses

Both unicellular and multicellular organisms are highly dependent on molecular mechanisms that allow a fast adaptation to environmental changes to enhance cell survival. In this context, the intestinal homeostasis is highly dependent on the maintenance of intestinal epithelial integrity. The intestinal epithelial layer comprises distinct cell types, such as absorptive epithelial cells, enteroendocrine cells, Goblet cells, Paneth cells, and stem cells whose optimal cell function is steadily challenged by external environmental factors, including diet and the microbiota <sup>43</sup>. In particular, the capacity to adapt to high levels of protein demand often decides cell fate, consequently affecting whole tissue homeostasis <sup>44-46</sup>. The UPR describes a physiological process contributing to the protein folding capacity of eukaryotic cells <sup>47</sup>. Herein, protein folding is supported by heat-shock proteins (HSP), also called chaperones, that bind to unfolded polypeptides enhancing their stabilization during protein structure formation <sup>48</sup>. Several protein families, such as specifically modified membrane proteins as well as secretory proteins, are synthesized along the ER and Golgi apparatus network <sup>49</sup>. In the cytoplasmic compartment protein folding is facilitated by HSP70, while structure formation in the ER is promoted by glucose-regulating peptide (GRP) <sup>78</sup> <sup>50, 51</sup>. Both HSP70 and GRP78 are ubiquitously expressed, but are associated with other proteins

defining a sensing complex for unfolded proteins. HSP70 forms complexes with the transcription factor heat shock factor (HSF) 1, while GRP78 is associated with the three ER transmembrane proteins activating transcription factor (ATF) 6, PKR-like ER kinase (PERK), and inositol requiring enzyme 1 (IRE1)<sup>50, 51</sup>. In case of enhanced protein demand mis- and malformed proteins can aggregate in the cytoplasm and the ER, respectively. Consequently, chaperones dissociate from their binding partners to support protein refolding. The release of the sensor proteins HSF1, ATF6, PERK, and IRE1 initiates the signaling cascade of the cytosolic UPR and the ER UPR, respectively<sup>50-52</sup>. Subsequently, specifically activated transcription factors facilitate the restoration of cellular homeostasis inducing the expression of UPR-related genes, such as chaperones (Figure 3)<sup>53</sup>.

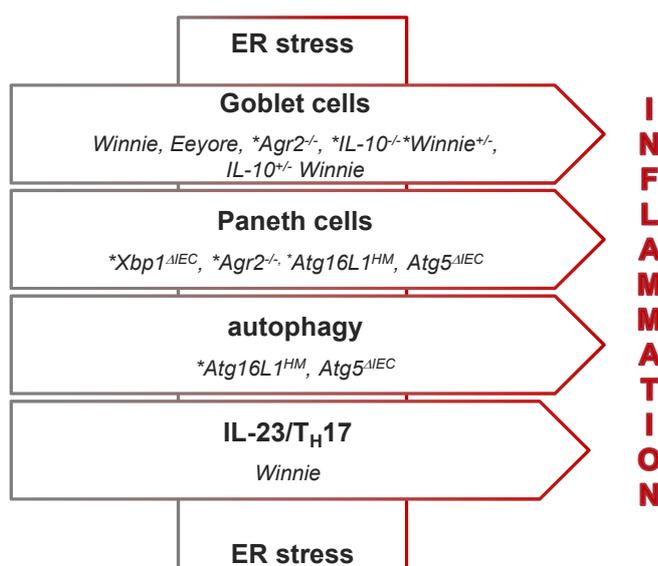

**Figure 3. Model of UPR in restoration of cell homeostasis.**

Under physiological conditions, specific sensors for incompletely folded proteins form inactive complexes with associated chaperones. Upon accumulation of malformed protein aggregates chaperones dissociate from their binding partners supporting protein structure formation. The release of the sensor proteins initiates a signaling cascade termed as UPR. The UPR leads to the activation and/or synthesis of specific transcription factors that in turn induce the expression of UPR-related genes, such as chaperones, to restore cellular homeostasis.

When the accumulation of mis- and malformed proteins exceeds the cellular protein folding capacity, sustained UPR activation aims towards apoptosis to eliminate unhealthy cells<sup>54, 55</sup>. In this context, unresolved UPR signaling might cause defective apoptosis strongly associated with the pathophysiology of IBD<sup>56</sup>.

### 1.3 UPR in IBD-associated processes

It is well known that ER stress plays a critical role in the pathogenesis of various diseases, such as diabetes, Alzheimer's disease, IBD, and cancer <sup>28, 57-61</sup>. GWAS with IBD patients have identified several ER stress-related genes, such as *cytoplasmic polyadenylation element binding protein 4 (CPEB4)*, *ORM1-like 3 (ORMDL3)*, *serine incorporator 3 (SERINC3)*, and *X-box binding protein 1 (XBP1)* as genetic factors that may affect the risk of IBD by deregulating ER UPR and apoptotic signaling under inflammatory conditions <sup>26, 28, 36, 62, 63</sup>. While dysfunction in the UPR-related XBP1 has been linked to the development of enteric inflammation, consequences of deregulated ORMDL3 (ER Ca<sup>2+</sup> homeostasis), CPEB4 (polyadenylation and translation of proteins), and SERINC3 (ER-Golgi stress) in IBD remain elusive <sup>28, 63-66</sup>. However, ER stress signaling has been observed in underlying mechanisms of IBD implicating in goblet cell homeostasis, Paneth cell function, autophagy, and T<sub>H</sub>17 cell-driven immune responses (Figure 4) <sup>28, 39, 67-70</sup>.

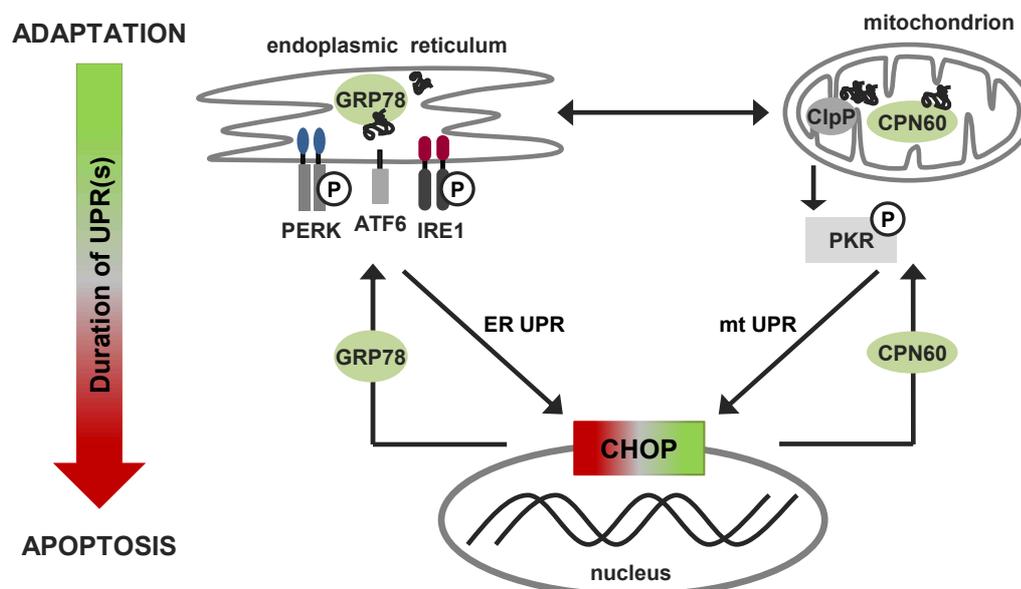

**Figure 4. ER stress-associated processes in intestinal inflammation.**

ER stress signaling has been found in IBD-associated processes using genetically modified mice with defects in goblet cell homeostasis, Paneth cell function, and autophagy. Genes identified as genetic risk variants for IBD are labeled with \*.

With regard to corresponding mouse models, ER stress in goblet cells has been linked to spontaneously developing colitis in Mucin 2 (MUC2)-deficient mice (*Winnie*, *Eeyore*, *IL-10<sup>-/-</sup>Winnie<sup>+/-</sup>*, *IL-10<sup>+/-</sup> Winnie*) <sup>68 71, 72</sup>. Furthermore, ER stress signaling has been observed in mice coping with spontaneous enteritis induced by disruption of goblet cell and Paneth cell function (*Agr2<sup>-/-</sup>*, *Xbp1<sup>ΔIEC</sup>*) <sup>28, 73</sup>. Of note, Paneth cell depletion has been further described in mouse models with defects in signaling pathways of autophagy. In this context,

signs of ER stress have been evaluated in intestinal inflammation in mice harbouring an IEC-specific deletion of *autophagy protein 5* (*Atg5<sup>ΔIEC</sup>*) and hypomorphic mutation in *autophagy-related protein 16-1* (*Atg16L1<sup>HM</sup>*), respectively <sup>74, 75</sup>.

It was previously reported that IEC-specific ER UPR further interrelates with IBD-associated mtUPR (Figure 5) <sup>40</sup>.

**Figure 5. ER and mtUPR converge at the level of CHOP expression.**

Both ER and mtUPR are initiated by aggregates of unfolded proteins leading to specific downstream signaling that is mediated by the ER-associated ER stress transducers PERK, ATF6, and IRE1 as well as mtUPR-dependent activation of PKR, respectively. Upon ER and mtUPR, the expression of chaperones, such as GRP78 and CPN60, is enhanced supporting adaptation by increasing the protein folding capacity of the organelles. Herein, the induction of CPN60 is driven by mtUPR-related CHOP protein expression. In contrast, CHOP protein expression appears highly associated with unsolved ER stress that consequently leads to the elimination of the unhealthy cell by initiating proapoptotic signaling (adapted from Rath et al., 2012).

The mtUPR is suggested to be activated by increased efflux of peptides into the cytosol promoted by the degradation of unfolded proteins from the mitochondrial matrix through the protease ClpP <sup>76</sup>. As a consequence, mitochondrial chaperones, such as chaperonin 60 (CPN60), are induced, thus promoting mitochondrial protein folding <sup>77</sup>. With regard to UPR signaling, mtUPR and the ER UPR converge at the level of CCAAT/enhancer-binding protein (C/EBP) homologous protein (CHOP) expression - one of the transcription factors highly associated with UPR-mediated apoptosis <sup>55, 78-80</sup>. CHOP, also called growth arrest- and DNA damage-inducible gene 153 (GADD153), is a basic leucine zipper (bZIP) tran-

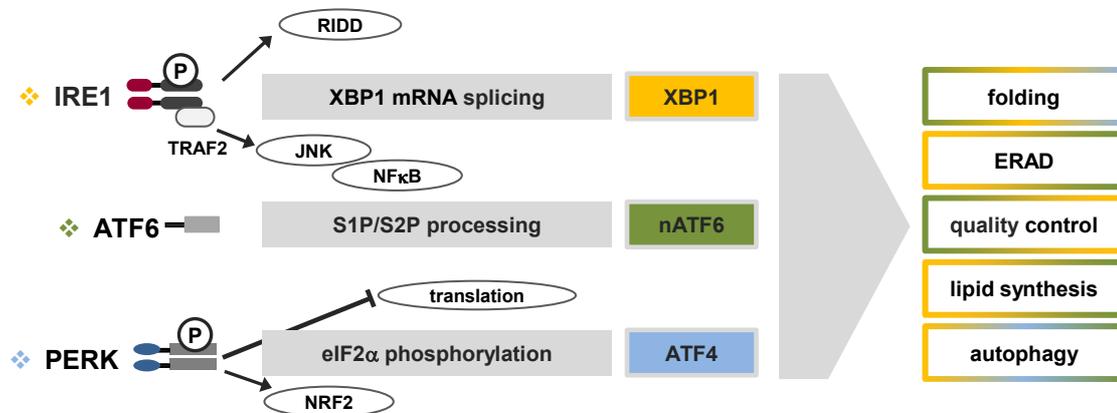

scription factor rarely expressed under physiological conditions. CHOP is induced in response to stress, including hypoxia, nutrient deprivation, and protein mis- and mal-folding in the ER and mitochondria, respectively<sup>40, 81-85</sup>. In the context of UPR, CHOP is reported to initiate cell apoptosis in late ER stress signaling, but, on the contrary, leads to an early increase of CPN60 in mtUPR<sup>78, 79, 86</sup>. Regarding the onset of inflammatory responses the cell-specific functions and consequences of ER UPR and mtUPR in IBD are poorly understood. Accordingly, the significance of CHOP expression in maintaining cellular homeostasis or inflammation-driven tissue pathology is completely unknown.

## 1.4 CHOP expression in ER UPR

### 1.4.1 The ER UPR

Being responsible for the correct folding of secretory proteins, membrane proteins, and proteins for the Golgi apparatus, lysosomes and others, as well as post-translational modifications, such as N-glycosylation and intra- and intermolecular disulfide bonds, respectively, the ER strongly contributes to cellular homeostasis by regulating distinct mechanisms to overcome harmful ER stress<sup>87-89</sup>. ER stress is defined as the unhealthy condition that is triggered by an enhanced demand of proteins that exceeds the protein folding capacity of the organelle, thus leading to the accumulation of aggregated proteins negatively influencing the ER function<sup>89-93</sup>. Mis- and mal-folded proteins are recognized by the three ER stress transducers ATF6, IRE1, and PERK that initiate a signaling network known as the ER UPR<sup>94-97</sup>. Under physiological conditions, these sensor proteins form inactive complexes with the luminal bound chaperone GRP78 that consequently dissociates from its binding partner when incomplete protein folding leads to ER stress<sup>98-101</sup>. The dissociation of GRP78 results in oligomerization of both transmembrane protein kinases IRE1 and PERK followed by autophosphorylation and specific downstream signaling. In contrast, liberated ATF6 translocates to the Golgi apparatus, where the activated transcription factor nATF6 is released after subsequent proteolysis through the site-1 protease (S1P) and the site-2 protease (S2P). The ER UPR comprises distinct interacting mechanisms to regain organelle and cell homeostasis (Figure 6). First, early ER stress responses diminish the accumulation of mal-folded proteins by inducing a PERK signaling-dependent shut-off of protein translation. Enhanced degradation of mRNA encoding for various ER-located proteins is further mediated by the PERK-dependent regulated IRE1-dependent decay (RIDD)<sup>94, 102-104</sup>. Second, IRE1 $\alpha$ -dependent JUN N-terminal kinase (JNK) pathway enables the activation of autophagy strongly suggested to eliminate protein aggregates and damaged ER, respectively, through the lysosomal pathway<sup>105</sup>. The removal of incompletely folded proteins is further supported

by the ER-associated degradation (ERAD), which is highly associated with mechanisms underlying protein quality control<sup>95, 106, 107</sup>.

**Figure 6. Downstream signaling in ER UPR.**

First ER stress responses ameliorate protein load through degradation of mRNA by IRE1-mediated RIDD as well as PERK signaling-dependent translational inhibition. Upon activation and/or synthesis of ER UPR-related transcription factors XBP1, nATF6, and ATF4, the expression of distinct genes is regulated supporting protein folding, ERAD, protein quality control, lipid synthesis, and autophagy.

When ER stress could not be resolved, sustained UPR signaling leads to the expression of pro-apoptotic genes that trigger the elimination of exhausted cells. Herein, the induction of CHOP expression is crucially involved in cell fate<sup>54, 80</sup>. Upon ER stress, CHOP is transcriptionally regulated by the activation of PERK and ATF6, respectively, but also signaling downstream of IRE1 contributes to CHOP expression<sup>102, 108, 109</sup>.

### 1.4.2 Regulation of CHOP expression in ER UPR

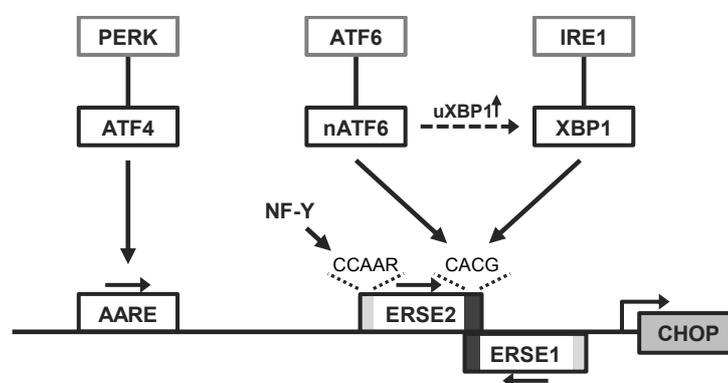

In response to ER stress, distinct transcription factors are synthesized or activated along the signaling axis of IRE1, ATF6, and PERK, such as XBP1, nuclear ATF6 (nATF6), and ATF4<sup>90, 99, 102</sup>. These transcription factors bind to several promoter elements, such as ER stress element (ERSE) I and II, UPR element (UPRE), cAMP response element (CRE), antioxidant response element (ARE), and amino-acid-regulatory element (AARE) I and II, thus driving the expression of UPR-related genes<sup>110-114</sup>. During prolonged ER stress responses, elimination of unhealthy cells is mediated by at least three pro-apoptotic pathways, such as activation of the JNK pathway, activation of ER-associated capsase-12, and transcriptional activation of CHOP<sup>86, 115</sup>. At least one AARE and two ERSE motifs could be identified in the human CHOP promoter, whereas latter reveal high homology with ERSE motifs found in the promoter region of other UPR-related genes, such as GRP78, GRP94, protein disulfide isomerase (PDI), and calreticulin<sup>111, 116-118</sup>.

Regarding the three branches of the ER UPR, the PERK pathway appears most relevant in CHOP induction (Figure 7)<sup>102, 119</sup>. The type I transmembrane kinase PERK is activated through the dissociation of GRP78 from its luminal domain<sup>96</sup>. Upon oligomerization and autophosphorylation, activated PERK in turn mediates phosphorylation of substrate proteins, thus initiating distinct signaling pathways that contribute to the resolution of ER stress<sup>95, 120-123</sup>. Herein, eukaryotic initiation factor-2 $\alpha$  (eIF2 $\alpha$ ) is phosphorylated on Ser51 that consequently results in an attenuation of general protein synthesis, even though there is limited translation of several short upstream open reading frames (uORF). Accordingly, ATF4 mRNA is translated due to its small uORF within the 5' untranslated region<sup>124</sup>. The transcription factor ATF4 can bind to the AARE core sequence 5'-AATGCATCA-3' which triggers the expression of CHOP in late ER stress responses<sup>86</sup>. Although both nATF6 and XBP1 have been shown to induce the expression of CHOP in response to ER stress, studies in PERK<sup>-/-</sup> cells and eIF2 $\alpha$ <sup>S51A</sup> cells, respectively, strongly suggested that CHOP induction is mainly regulated by the PERK/eIF2 $\alpha$  pathway<sup>102, 119</sup>.

However, induction of CHOP expression through nATF6 and XBP1 is mediated by binding of these transcription factors to the CACG part of the ERSE consensus sequence 5'-CCAAT-N<sub>9</sub>-CCACG-3'. In mammalian cells, ATF6 termed for the two isoforms ATF6 $\alpha$  and ATF6 $\beta$ , but further represents a group of ATF6 homologues bZIP transcription factors including LUMEN/CREB3, CREB4, OASIS/CREB3L1, BBF2H7/CREB3L2, and CREBH/CREB3L3, respectively, that are similarly processed upon ER UPR<sup>125, 126</sup>. Liberated ATF6 translocates to the Golgi apparatus, where it is transformed into an active bZIP transcription factor nATF6 through proteolytic processing catalyzed by the two proteases S1P and S2P<sup>99</sup>. ATF6-dependent signaling is mediated through the binding of nATF6 to

distinct promoter elements, such as ERSE I and II, UPRE, and CRE. Accordingly, nATF6 induces the expression of genes encoding UPR-related components for protein folding, such as GRP78, and protein degradation, respectively<sup>108, 127</sup>. Activation of CHOP transcription is triggered by both nATF6 dimers and heterodimers formed with constitutively expressed NF-Y that binds to the CCAAR part of the ERSE motif. Furthermore, the activation of the ATF6 branch contributes to CHOP expression by the induction of unspliced XBP1 (XBP1u) transcription, one of the main targets of activated IRE1.

The IRE1 pathway displays the most conserved UPR signaling pathway in eukaryotic cells<sup>90</sup>. Notably, higher eukaryotes possess two forms of IRE1. IRE1 $\alpha$  is ubiquitously expressed, while IRE1 $\beta$  appears tissue-specifically expressed in epithelial cells<sup>109, 128-131</sup>. Like PERK, IRE1 is known as an atypical type I transmembrane protein kinase that further reveals endoribonuclease activity<sup>90</sup>. Upon ER stress, GRP78 dissociation uncovers the ER luminal dimerization domain of IRE1 that drives the oligomerization and subsequently the activation of IRE1 by autophosphorylation of the cytosolic RNase domain<sup>132, 133</sup>. The active endoribonuclease converts XBP1u mRNA into the spliced form XBP1s. The removal of a 26 nucleotide intron leads to a frame shift in the coding sequence of XBP1 resulting in the translation of the 54 kDa bZIP transcription factor XBP1 with potential transcriptional activity<sup>51, 64</sup>.

**Figure 7. Induction of CHOP mRNA expression during ER UPR according to Oyadomori et al. (2007).**

The promoter site of *Chop* presents at least one AARE motif and two ERSE motifs, through which the expression of CHOP is regulated upon ER stress signaling. Binding to the AARE results from activation of the UPR branch PERK/ATF4, while binding to ERSE is promoted by the induction of the ATF6 and IRE1 signaling pathways, respectively. nATF6 binds as dimers and/or heterodimers formed with constitutively expressed NF-Y, while XBP1 exclusively binds to the ERSE motif as heterodimers with NF-Y. Arrows indicate specific binding sites of nATF6/XBP1 (CACG) and NF-Y (CCAAR) within the ERSE motif.

XBP1 can bind to both the ERSE and UPRE sequence 5'-TGACGTGG-3' in interaction with NF-Y, thus leading to the expression of genes encoding for chaperones, such as

GRP78, and genes contributing to ERAD, ER quality control, and membrane biogenesis<sup>110, 134-137</sup>. Even though XBP1/NF-Y complexes reveal low affinity to ERSE motifs, CHOP expression may also occur in response to IRE1 activation<sup>109</sup>.

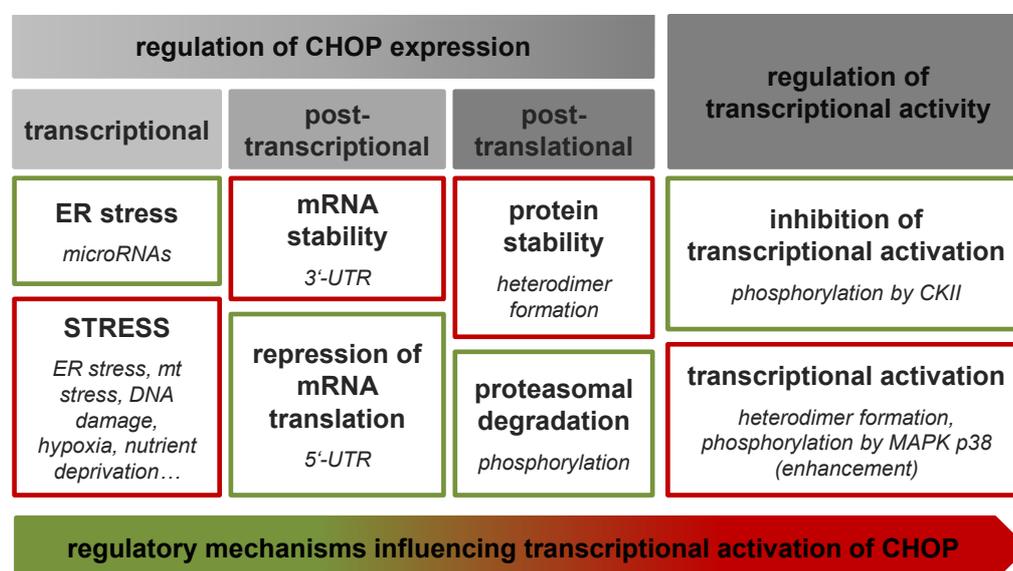

Taken together, the expression of CHOP is strongly suggested to be regulated by the ER UPR branch PERK/eIF2 $\alpha$ . In this regard, EIF2 $\alpha$  kinases, such as PERK, RNA-activated protein kinase (PKR), general control nonderepressible kinase 2 (GCN2), and heme-regulated inhibitor kinase (HRI), are commonly known to implicate in translational inhibition under stress conditions<sup>96, 138-141</sup>. Of those, PKR has been clearly demonstrated to contribute to ER stress-mediated apoptosis through the activation of the signaling pathway eIF2 $\alpha$ /ATF4/CHOP<sup>142</sup>. Most recently, PKR has been shown to impact on intestinal inflammation upon mitochondrial stress signaling. In this context, studies on interrelated signaling pathways revealed that ER UPR and mtUPR converge at the level of CHOP expression<sup>40</sup>.

### 1.5 CHOP expression in mtUPR

In mammalian cell culture, mtUPR can be specifically induced by the transfection of truncated ornithine transcarbamylase (OTC $\Delta$ ). As a consequence, OTC $\Delta$ -driven mtUPR causes the expression of genes encoding mitochondrial *Cpn60* and *Cpn10*, but further leads to the expression of CHOP<sup>78, 143, 144</sup>. CHOP as well as CHOP dimer partner C/EBP $\beta$  were found to be regulated by the mtUPR responsive element AP-1, which in turn strongly suggested interrelated mitochondrial and nuclear signaling pathways at the level of JNK2 activation<sup>78</sup>. CHOP/C/EBP $\beta$  dimers were shown to induce further mtUPR responsive genes, whereas gene activation seemed to be tightly regulated by conserved mtUPR elements (MURE) flanking corresponding promoter sites<sup>78, 79</sup>. Binding of CHOP to the *Cpn60* promoter contributes to *Cpn60* induction<sup>78, 144</sup>. Thus, CHOP expression is strongly suggested to be an early event upon mtUPR, which is in stark contrast to the expression patterns of CHOP in response to ER UPR signaling.

## 1.6 Molecular features of CHOP

CHOP, also termed GADD153 and DNA-damage-inducible transcript 3 (DDIT3), is a bZIP transcription factor that belongs to the family of C/EBPs<sup>81, 145</sup>. CHOP is a ~29 kDa protein comprising a N-terminal putative transactivation domain and a C-terminal bZIP domain that contains a DNA-binding basic region and a leucine zipper dimerization domain<sup>81, 146</sup>. CHOP is known to be rarely expressed under physiological conditions, but is induced in response to cellular stress, such as hypoxia, nutrient deprivation, as well as ER and mtUPR<sup>81-85, 144</sup>. The expression of CHOP is mainly regulated at the transcriptional level, but mRNA as well as protein levels are tightly controlled by post-transcriptional and post-translational regulation patterns (Figure 8). At the transcriptional level, the induction of CHOP expression correlates with increasing cellular stress. In this context, CHOP expression has been shown to be dependent on stress underlying mechanisms controlling both activation and inhibition of Chop promoter<sup>118, 147</sup>. Post-transcriptional regulation of CHOP expression is mediated by mRNA stability. The highly conserved 5'-untranslated region (UTR) of CHOP mRNA has been implicated in the regulation of CHOP translation, while binding of conserved 3'-UTR to Methionyl-tRNA Synthase pre-mRNA was suggested to impact on the mRNA stability of CHOP<sup>148, 149</sup>.

**Figure 8. Regulatory mechanisms underlying the expression and transcriptional activation of CHOP.**

CHOP expression is regulated at the transcriptional, post-transcriptional, and post-translational level. Transcriptional activation of CHOP protein is mainly mediated by phosphorylation and heterodimer formation. Green labeled regulatory elements lead to the reduction, red labeled elements to an increase of CHOP expression and transcriptional activation, respectively.

Distinct post-translational modifications have been described affecting CHOP protein expression levels as well as its transcriptional activation. In this regard, phosphorylation of CHOP protein appears crucial for both regulation patterns. Inhibitory effects on the transcriptional activation has been shown for CHOP phosphorylation through casein kinase II (CKII) <sup>150</sup>. In contrast, phosphorylation of CHOP on serine-residues 79/82 (human) and 78/81 (rodents) by p38 mitogen activated protein (MAP) kinase has been demonstrated to enhance the transcriptional activation of CHOP protein upon ER stress <sup>151</sup>. The transcriptional activation of CHOP is further dependent on heterodimer formation, which in turn protects CHOP against proteasomal degradation <sup>81, 152-157</sup>. CHOP protein constitutively undergoes polyubiquitination that is triggered by phosphorylation of the N-terminal portion <sup>153</sup>. Polyubiquitination and subsequent degradation by the proteasome is suppressed by dimer formation with other C/EBPs, whereas formation of CHOP dimers has not been reported so far <sup>152 146</sup>.

However, various regulatory mechanisms seem to limit the expression of CHOP under physiological conditions, while both expression and transcriptional activation are tightly controlled in response to stress. In this regard, CHOP has been strongly suggested to be a key regulator of cell fate.

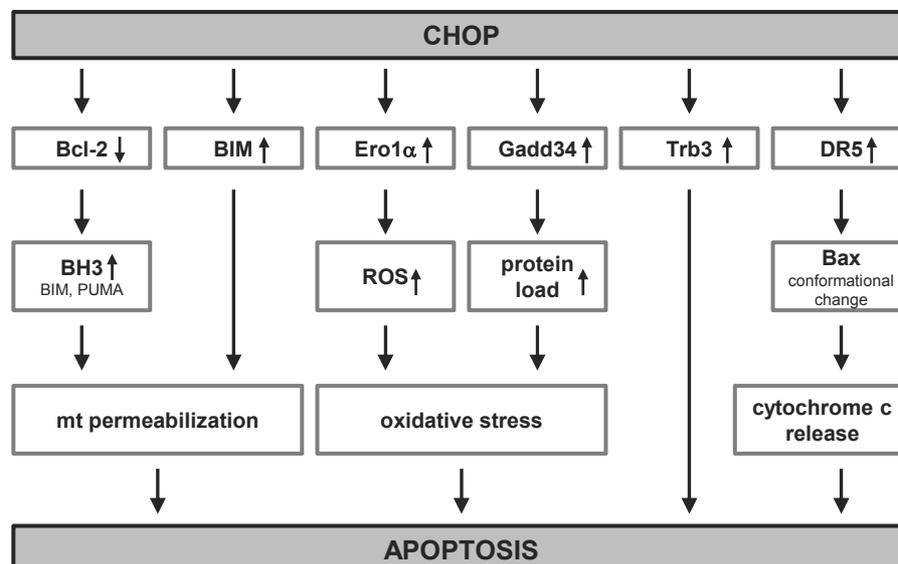

## 1.7 Consequences of CHOP protein expression

CHOP has been originally described as a DNA damage-inducible gene highly associated with cell growth arrest <sup>81, 158-160</sup>. Shortly thereafter, CHOP has been linked to ER stress-induced apoptosis upon sustained UPR signaling <sup>54, 108</sup>. In this context, CHOP is suggested to be crucially involved in the interplay between disease-related ER stress and apoptosis in degenerative disorders <sup>60, 161-163</sup>. With regard to intestinal inflammation, down-regulation of CHOP mRNA and protein expression in inflamed mucosal tissue indicated that regulation of CHOP is most likely dissociated from UPR signaling as well as ER stress-mediated apoptosis in UC patients <sup>28, 164, 165</sup>. In contrast to that, studies on complete CHOP knock-out mice (*CHOP*<sup>-/-</sup>) demonstrated that CHOP deficiency leads to protection against intestinal apoptosis associated with reduced inflammation in response to DSS- and 2,4,6-trinitrobenzene-sulfonic acid (TNBS)-induced colitis <sup>166</sup>. Following these discrepancies, recently published data further indicated that CHOP implicates in the protection of hyperoxia-induced lung injury in mice, thus demonstrating that even the effects of enhanced CHOP expression are not restricted to cell death-promoting mechanisms <sup>167</sup>. In this regard, CHOP has been shown to be regulatory involved in mechanisms underlying the proliferative capacity of cells independent of cell death-promoting signals <sup>160, 168</sup>.

However, it is worth mentioning that changes in both proliferation and apoptosis have been observed in IECs of UC patients <sup>169, 170</sup>. Even though CHOP expression has not been correlated to epithelial cell-specific proliferation and/or apoptosis so far, it is sufficiently characterized in terms of apoptosis and has been further described in the context of proliferative regulation.

### 1.7.1 CHOP and apoptosis

Strong evidence accumulated demonstrating a pro-apoptotic role for CHOP protein <sup>54, 171</sup>. Herein, both transcriptional activation and nuclear translocation of CHOP appear dependent on heterodimer formation, but seem rather enhanced by stress-induced protein phosphorylation on serine-residues 78 and 81 through the MAP kinase p38 <sup>81, 151, 155-157</sup>. Dimers are most prominently formed with both isoforms of C/EBP $\beta$  - liver activating protein (LAP) and liver inhibitory protein (LIP), but also with C/EBP $\alpha$  and members of the ATF family, including ATF3 and ATF4, which promotes the binding of unique DNA recognition sites inducing the expression of specific genes downstream of CHOP <sup>172</sup>. Genes, such as *Bcl-2*, *Bim*, *Ero1 $\alpha$* , *Gadd34*, *DR5*, and *Trb3*, have been reported to be regulated by CHOP protein, thus driving apoptosis in unhealthy cells (Figure 9) <sup>80, 173-176</sup>.

**Figure 9. Pro-apoptotic signaling downstream of CHOP.**

ER stress-induced CHOP protein expression leads in turn to the regulation of CHOP target genes, such as *Bcl-2*, *BIM*, *Ero1 $\alpha$* , *Gadd34*, *Trb3*, and *DR5*, highly associated with pro-apoptotic signaling.

According to studies in mammalian cell lines demonstrated that the presence of CHOP/LIP heterodimers leads to down-regulation of pro-survival Bcl-2<sup>156, 173</sup>. Although direct implications of CHOP in Bcl-2 suppression remain elusive, decreased expression of Bcl-2 subsequently results in enhanced levels of BH3-only proteins, such as BIM and PUMA both contributing to mitochondrial permeabilization and apoptosis<sup>177</sup>. Furthermore, up-regulation of BIM has been shown to contribute to ER stress-mediated apoptosis, whereas elevated BIM levels were induced by decreased proteasomal degradation as well as increased gene expression triggered by CHOP-C/EBP $\alpha$  heterodimers<sup>178</sup>.

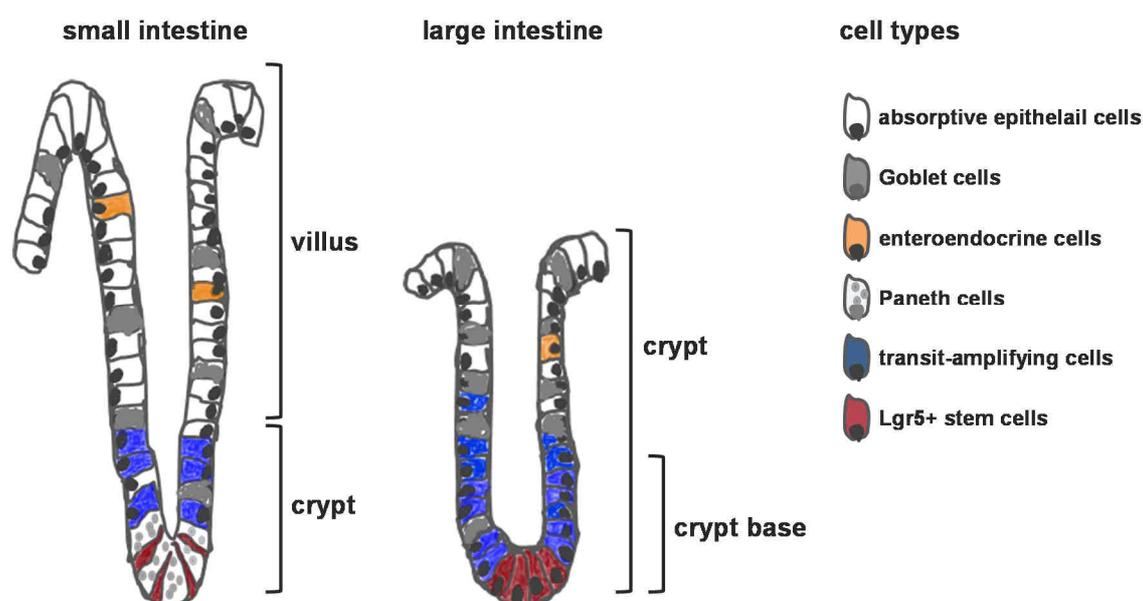

CHOP-mediated apoptosis is widely cited in response to unresolved ER stress, which is further associated with oxidative stress<sup>80</sup>. Under physiological conditions, the oxidative environment of the ER lumen supports post-translational modification of proteins, such as disulfide bond formation. ERO1 proteins, including ERO1 $\alpha$ , appear mechanistically involved in maintaining an adequate redox state in the ER lumen<sup>179</sup>. Upon prolonged ER stress, CHOP-induced ERO1 $\alpha$  expression might contribute to hyperoxidizing conditions in the ER lumen, thus promoting H<sub>2</sub>O<sub>2</sub> leakage into the cytosol and subsequent formation of cytotoxic reactive oxygen species (ROS)<sup>80, 180</sup>. As a consequence, oxidative stress can cause more severe cellular stress and cell death by amplifying CHOP expression in response to enhanced PKR activation<sup>40, 180</sup>. It has been demonstrated that both ER stress as well as ER-related oxidative stress appeared sufficiently decreased upon eIF2 $\alpha$ -mediated translation attenuation. Upon UPR signaling, translational inhibition is reversed by GADD34 whose cellular expression is tightly controlled by proteasomal degradation<sup>121, 122, 181</sup>. Thus, CHOP-dependent accumulation of GADD34 highly enhances the protein load subsequently leading to oxidative stress and apoptosis<sup>80, 182</sup>.

Further genes that have been described in causing ER stress-mediated cell death are *DR5* and *Trb3*. *DR5* and *Trb3* are expressed in a CHOP-dependent manner when cells were treated with the ER stress inducers thapsigargin and tunicamycin, respectively<sup>175, 176</sup>. Although less is known about the pro-apoptotic mechanisms of Trb3, DR5 is strongly suggested to have an effect on the conformational change of Bax that in turn promotes cell death through the release of apoptogenic proteins including cytochrome c<sup>176, 183, 184</sup>.

Under physiological conditions, apoptosis is described as a tightly regulated process that enables tissue regeneration in order to overcome cellular dysfunction<sup>185</sup>. In this regard, the renewal of the intestinal epithelial layer is characterized by strictly controlled proliferative and apoptotic events promoting a balance between turnover and shedding of epithelial cells<sup>186</sup>. As a consequence, both defective apoptosis and/or proliferation could cause an imbalance in tissue regeneration, thus leading to changes in epithelial integrity.

### 1.7.2 CHOP and proliferation

The intestinal epithelium is renewed every 3-5 days <sup>187</sup>. Self-renewal is organized by stem cell compartments located in the crypts of the small and large intestine, respectively <sup>188</sup>. Intestinal stem cells have been well characterized as crypt base-located Leucine-rich repeat-containing G-protein coupled receptor 5 (Lgr5)-positive cells that give origin to all cell types of the epithelial layer, including absorptive epithelial cells (enterocytes), goblet cells, Paneth cells, and enteroendocrine cells (Figure 10) <sup>43, 188</sup>. In principle, Lgr5-positive cells divide to adjacent transit-amplifying (TA) cells that in turn lose their proliferative capacity during terminal differentiation. Within 3-4 days, mature epithelial cells migrate toward the intestinal lumen, undergo programmed cell death, and are finally shed into the lumen the time when dead cells had been replaced by new ones <sup>186</sup>. In contrast to that, cells differentiated into Paneth cells remain located in the crypt base to constitute the niche for Lgr5-positive cells <sup>189</sup>.

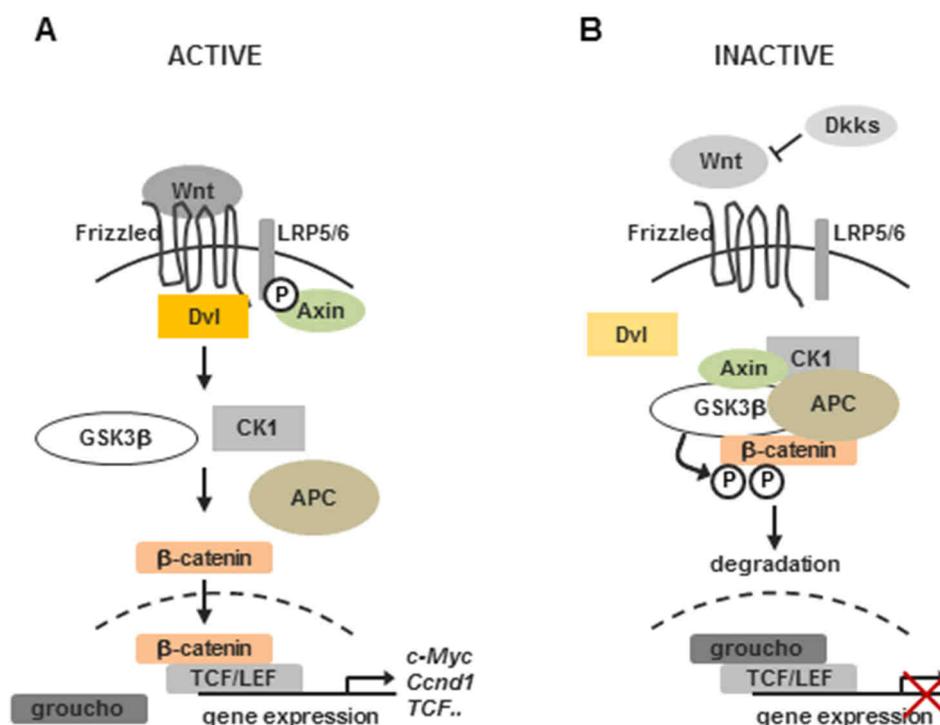

**Figure 10. Cell types in small and large intestine.**

The intestine comprises distinct cell types, such as crypt base-located stem cells, transit-amplifying cells, and differentiated cells, such as absorptive epithelial cells, enteroendocrine cells, mucus-producing goblet cells, and Paneth cells.

It was recently reported that UPR signaling implicates in the differentiation of IECs <sup>42</sup>. In this context, it has been shown that TA cells contain higher basal mRNA expression levels of ER stress responsive genes than Lgr5-positive stem cells <sup>42, 190</sup>. Increased expression of Grp78, Atf6, Xbp1, Perk, Atf4, and CHOP was highly associated with down-regulation of stem cell marker, such as Ascl2, Olfm4, and Myc. In turn, induction of ER stress in stem cells led to the loss of stemness, which was strongly attributed to signaling downstream of

PERK<sup>42</sup>. In this regard, previous studies demonstrated that ER stress-dependent eIF2 $\alpha$  phosphorylation promotes cell cycle arrest by inhibiting the translation of Cyclin D<sup>191-193</sup>. Cell cycle arrest has further been shown to be induced in response to enhanced CHOP protein expression<sup>160</sup>. Although an implication of CHOP in intestinal epithelial stemness and/or proliferative potential of IECs remains elusive, previous studies described a role for CHOP in the inhibition of Wnt/TCF signals<sup>194</sup>. Wnt signaling has been demonstrated to play an essential role in the epithelial stem cell compartment of the intestine<sup>195</sup>. In principle, activation of the canonical Wnt pathway leads to the induction of distinct target genes, such as *c-Myc* and *Cyclin D*, thus supporting cell cycle progression and proliferation, respectively (Figure 11)<sup>196-198</sup>.

**Figure 11. Canonical Wnt signaling leads to the expression of genes promoting cell cycle progression.**

(A) Wnt binding to Fizzled receptors initiates a signaling cascade that mediates the stabilization and nuclear translocation of  $\beta$ -catenin. Subsequently,  $\beta$ -catenin forms transcriptionally active complexes with TCF proteins, thus inducing the expression of Wnt target genes, such as *c-Myc*, *Ccnd1*, and TCF. (B) In the absence of Wnt binding,  $\beta$ -catenin is phosphorylated by GSK3 $\beta$ , which induces  $\beta$ -catenin degradation through the proteasome. Transcriptional activation of TCF proteins is suppressed by complex formation with *groucho*.

Wnt binding to membrane-associated Fizzled receptors initiates a signaling cascade that mediates stabilization and nuclear translocation of  $\beta$ -catenin. Nuclear  $\beta$ -catenin forms transcriptionally active complexes with members of the T cell factor (TCF) family, which pro-

motes the expression of Wnt target genes. In the absence of Wnt binding,  $\beta$ -catenin undergoes proteasomal degradation in the cytoplasm, while TCFs form inactive complexes with repressors, such as groucho. Modification of the Wnt signaling cascade through the depletion of TCF4 and  $\beta$ -catenin, respectively, as well as overexpression of Dickkopf (DKK) 1 leads to the loss of proliferative potential of intestinal crypts<sup>195, 199, 200</sup>. Studies in *Xenopus laevis* revealed that high CHOP protein expression inhibited the embryonic development. In this context, CHOP is strongly suggested to impact on Wnt signaling at the level of TCF, thus suppressing the expression of Wnt target genes, including *c-Myc*<sup>194</sup>.

Taken together, CHOP is an important regulator of proliferation and apoptosis. Dysregulation of both cellular events have been strongly associated to imbalanced epithelial turnover rates, thus negatively affecting epithelial integrity<sup>201</sup>. In this regard, mechanisms underlying the regulation of CHOP protein expression, including ER stress signaling could be crucially involved in the onset of inflammation, thereby contributing to the disease phenotype of IBD.

## 2 Study objective

While both ER UPR and mtUPR have been implicated in chronic intestinal inflammation, functional correlation between interrelated signaling pathways and inflammation-related disease susceptibility remains to be elucidated at a tissue-specific level. Despite the fact that ER UPR and mtUPR converge at the level of CHOP expression, the significance of this transcription factor in maintaining cellular homeostasis or promoting inflammation-associated tissue pathology is completely unclear. Since CHOP mRNA and protein expression appears down-regulated under inflammatory conditions in UC, we suggested that UPR-related CHOP expression is regulated in an apoptosis-independent fashion.

Hence, we aim to investigate the functional consequences of enhanced CHOP protein expression in a tissue-specific resolution beyond single cell-mediated effects obtained in cell culture. We generated *Chop*<sup>IEC Tg/Tg</sup> mice overexpressing CHOP protein in the intestinal epithelium that were characterized under normal and disease-related conditions of experimental colitis, thus elucidating the relevance of UPR-related CHOP protein in the disease-conditioning of intestinal inflammation.

## 3 Material and methods

### 3.1 Molecular biological methods

#### Generation of HA-tagged CHOP

The plasmid construct pBluescript containing HA-tagged CHOP was generated by Emanuel Berger. It was provided to Taconic for the generation of the *Chop*<sup>Rosa26 flox/flox</sup> mouse model. Total RNA was extracted from C57BL/6N embryo 7.5 dpc (Macherey-Nagel GmbH & Co.KG, Düren, Germany) and cDNA library was generated by using SuperScript® Reverse Transcriptase (Life Technologies, Karlsruhe, Germany). Cloning of Gadd153 cDNA was performed by using primer pairs *for\_5'-tatcatgttgaagatgagcgggtg-3'*, *rev\_5'-caat-gtaccgtc-tatgtgcaagcc-3'* and *for\_5'-agaattcaccatggcagctgagtcctgc-3'*, *rev\_5'-agcggccgct-gcttggtg-cagg-3'* (Sigma-Aldrich, Taufkirchen, Germany). PCR product and HA-tag oligomer were digested with NotI and ligated using Quick Ligation Kit following manufacturer's instructions (New England Biolabs, Frankfurt, Germany). Ligation product was amplified by using primers *for\_5'-agaattcaccatggcagctgagtcctgc-3'*, *rev\_5'-aggatccctaagcgtaatctggaa-catcg-tatggg-3'* and inserted into pBluescript xy by using EcoRI and BamHI restriction sites (New England Biolabs, Frankfurt, Germany).

#### Generation of pcDNA3.1(-)-Hygro-CHOP-HA and mutated plasmid constructs

For mammalian cell culture experiments, CHOP-HA was cut off pBluescript and inserted into pcDNA3.1(-)-Hygro by using EcoRI and BamHI restriction sites. Site-directed mutagenesis of CHOP-HA was performed by overlap extension PCR using Phusion Hot Start II High-Fidelity DNA Polymerase (New England Biolabs, Frankfurt, Germany). PCR reactions were performed using cycle conditions: 1x 3 min at 95°C; 25x 1 min at 95°C, 1 min at 52°C, 1 min at 72°C; 1x 7 min at 72°C. Primers that were used for the generation of CHOP-HA mutants [S14/15A], [S30/31A], [S78/81A], [S14/15A, S30/31A], and [S14/15A, S30/31A, S78/81A] are listed in Table 1.

PCR products were digested using restriction enzymes BamHI and XhoI and ligated with pcDNA3.1(-)-Hygro. Sequencing of plasmid constructs was performed by GATC. Sequence data and alignments are listed in Supplementary materials.

### Gene expression analysis

Total RNA was isolated using column-based NucleoSpin® RNAII kit (*Macherey-Nagel GmbH & Co. KG, Düren, Germany*) according to the manufacturer's instructions. Complementary DNA was prepared using random hexamer primers and SuperScript™ First-Strand Synthesis System (*Life Technologies GmbH, Karlsruhe, Germany*). Quantification of gene expression was performed on LightCycler® 480 System using the Universal ProbeLibrary System (*Roche Diagnostics GmbH, Mannheim, Germany*) and gene-specific primers (*Sigma-Aldrich, Taufkirchen, Germany*) (Table 2 and 3).

### Microarray analysis

Total RNA was prepared from primary colonic epithelial cells of *Chop*<sup>EC Tg/Tg</sup> mice and wild-type controls with an age of 12 weeks (n = 8 per group) as well as DSS-treated male mice (3d 2% DSS, 5d 2% DSS plus 5d H<sub>2</sub>O, n = 5-6) with column-based NucleoSpin® RNAII kit (Macherey-Nagel GmbH & Co. KG, Düren, Germany) according to the manufacturer's instructions. RNA concentration and quality was determined by spectrophotometric analysis (ND-1000, PEQLAB Biotechnologie GmbH, Erlangen, Germany). RNA integrity number (RIN) was >8 for all samples (Agilent bioanalyzer, Alpha Metrix Biotech GmbH, Rödermark, Germany). Labeling of total RNA (100ng) was performed with the Ambion WT Expression kit (Life Technologies, Bleiswijk, The Netherlands), samples were hybridized to Affymetrix GeneChip Mouse Gene 1.1 ST arrays (Affymetrix, Santa Clara CA) and scanned on an Affymetrix GeneTitan instrument. Probes are annotated using up-to-date databases and assigned to unique gene identifiers, in this case Entrez IDs. The probes present on the mouse Gene 1.1 ST arrays represent 21.225 Entrez IDs. Arrays were normalized with the Robust Multi-array Average method. Only probe sets with normalized signal intensities above 20 on at least five arrays, interquartile range > 0.15 and at least 7 probes per probeset were selected for further analysis. Enriched pathways and gene ontology (GO) groups were identified by using the GeneRanker tool in the Genomatix Genome Analyzer. Additional analysis on GO terms was performed by using WEB-based GENE SeT AnaLysis Toolkit <sup>202</sup>. Heat map generation and hierarchical clustering analysis was performed by using MultiExperiment Viewer (TM4 microarray software suite) <sup>203</sup>.

## 3.2 Cell culture methods

### Cell lines and media

Cell culture experiments were performed using the colonic epithelial cell line ptk6 (passage 40-50) kindly provided by R. Whitehead (Vanderbilt University, Nashville) <sup>204</sup>. Non-differentiated ptk6 cells were grown in RPMI 1640 medium containing 5% FCS, 1% insulin/transferrin/selenium, interferon- $\gamma$  (2ng/ml), and 2 mM L-glutamine (all Life Technologies, Karlsruhe, Germany) under a humidified atmosphere and 5% CO<sub>2</sub> at 33°C. For differentiation, ptk6 cells were cultured for at least 5 days in media lacking interferon- $\gamma$  under a humidified atmosphere and 5% CO<sub>2</sub> at 37°C. Ptk6 cell lines containing mutated plasmid constructs were grown in media additionally supplemented with hygromycin B (500 $\mu$ g/ml).

### Transient transfection

Plasmid DNA transfection was performed by using Fugene 6 (Promega, Mannheim, Germany) according to the manufacturer's instructions. Therefore, cells showing 50% confluency were incubated with a mixture containing plasmid DNA and Fugene 6 reagent in a ratio of 1:3 (0.5  $\mu$ g plasmid DNA per 24-well) for 24h followed by an expression time for 14h. Data are presented giving entire transfection time of 38h.

### Generation of polyclonal cell lines ptk6:CHOP-HA, ptk6:S78/81A, ptk6:ctrl

Plasmid DNA transfection was performed by using Fugene 6 (Promega, Mannheim, Germany) according to the manufacturer's instructions. Ptk6 cells were grown in a T-75 flask and transfected with pcDNA3.1(-), pcDNA3.1(-)-CHOP-HA, and pcDNA3.1(-)-S78/81A when cells were grown to 50% confluency. Transfection medium was removed after 48h and selection medium was applied containing hygromycin (500  $\mu$ g/ml). Polyclonal ptk6 cell line was generated by changing selection medium every 1-3 days until cells were grown to confluency. Newly generated cell lines were at least cultivated for 5 passages before being used in an experiment.

### Inhibition of proteasomal degradation by Lactacystine

Non-differentiated ptk6 cell were transiently transfected with pcDNA3.1(-)-CHOP-HA for 24h. Cell medium was changed and proteasome inhibitor Lactacystine (Sigma-Aldrich, Taufkirchen, Germany) was applied in a concentration of 10  $\mu$ M. After 3h and 6h of incubation cells were lysed in lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 2% CHAPS, 1% DTT (all from Roth, Karlsruhe, Germany), and protease inhibitor (Roche Diagnostics, Mannheim, Germany) for Western blot analysis.

**Determination of cellular proliferation rate by cell proliferation ELISA, BrdU**

Determination of cell proliferation was performed by using Cell Proliferation ELISA, BrdU (Roche Diagnostics, Mannheim, Germany). Non-differentiated ptk6 cells were seeded into 96-well plates with 1.000 cells/ml. Cell proliferation was determined for 5 days following the manufacturer's instructions. Doubling time was assessed calculating linear progression of received absorbance.

**Transwell experiments**

For transwell experiments ptk6 cells were cultivated in media without INF- $\gamma$  at 37°C. Ptk6 cells ( $3 \times 10^5$  cell/ml) were seeded into 0.4  $\mu$ m polyester Transwell inserts (Costar Corning, Corning, USA). Transepithelial electrical resistance (TEER) was measured using Volt-Ohm-meter by Millipore (Millipore, Schwalbach/TS, Germany) following the manufacturer's instructions.

***In vitro* scratch wound healing assay**

Polyclonal cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A] ( $5 \times 10^4$  cells/ml) were seeded into a 96 well plate and cultivated in media without INF- $\gamma$  at 37°C to confluent monolayers. Four days after reaching confluency, ptk6 cells were scratched (1 scratch/well) using a 1 ml pipette tip. Cells were washed 2 times with PBS (Life Technologies, Karlsruhe, Germany) to remove cells in supernatants. Scratch size was monitored daily by microscopic analysis using the CKX41-combined DP26 camera system and the cellSens Digital Imaging Software (Olympus, Hamburg, Germany). Scratch closure was determined calculating scratch diameters in percentage to initial scratch size.

**Analysis of cell cycle by flow cytometry**

Polyclonal cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A] ( $2 \times 10^4$  cells/ml) were seeded into T-25 cell culture flasks (Sarstedt AG & Co., Nümbrecht, Germany) and cultivated in media supplemented with INF- $\gamma$  at 33°C. When cell monolayers reached 50% confluency, cells were detached using Trypsin/EDTA (Life Technologies, Karlsruhe, Germany) and resuspended by pipetting to single cells. 5 ml of medium was added and cells were centrifuged at 300g for 5 min. Cell pellets were resuspended in 5 ml ice-cold PBS (Life Technologies, Karlsruhe, Germany) and centrifuged at 300g for 5 min. Cell pellets were resuspended in 2 ml ice-cold 70% ethanol and incubated on ice for 1h. Cells were centrifuged at 300g for 5 min and washed twice with 1 ml ice-cold PBS. 100  $\mu$ l RNase-solution (100  $\mu$ g/ml in PBS) was added and cells were incubated for 5 min at RT. 800  $\mu$ l propidium iodide-solution (50  $\mu$ g/ml in PBS) was added and cells were incubated for additional 15 min at RT and 10 min at 37°C. Afterwards cell suspensions were stored on

ice. Flow cytometry was performed using FACSDiva software (BD Biosciences, Heidelberg, Germany) and cell cycle was analyzed using ModFit LT 3.0 (Verity Software House Inc., Topsham, ME).

### 3.3 Protein methods

#### Western blot analysis

Cells were lysed in protein lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 2% CHAPS, 1% DTT (all from Roth, Karlsruhe, Germany), and protease inhibitor (Roche Diagnostics, Mannheim, Germany). Total protein concentration of ultrasonicated samples was determined by Bradford Assay (Carl Roth GmbH & Co.KG, Karlsruhe, Germany) according to standard protocol. Sample volumes containing 10 µg and 20 µg of protein were diluted with 5x SDS buffer and incubated for 10 min at 95°C. 12.5% reducing sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) was performed (Biometra, Göttingen, Germany) followed by semi-dry blotting (PEQLAB Biotechnologie GmbH, Erlangen, Germany) using PVDF membranes (Merck KGaA, Darmstadt, Germany). Unspecific binding sites were blocked with 5% milk powder/1xTBS/0.1% Tween-20 (TBST) for 1 hour at RT. Primary antibody (Table 4) was incubated o/n at 4°C and HRP-conjugated secondary antibody was applied for 1h at RT (Table 5). The respective immunoreactive protein was detected by using an enhanced chemiluminescence light-detecting kit (GE Healthcare, Uppsala, Sweden).

**Table 4. List of primary antibodies used in Western blotting.**

antibody	dilution	ID	company
anti-HA	1:1000	14-6756	eBioscience, Frannkfurt, Germany
anti-CHOP	1:1000	sc-575	Santa Cruz Biotechnology, Heidelberg, Germany
anti-Reg3β	1:1000	AF5110	R&D Systems, Wiesbaden, Germany
anti-P-p38	1:1000	4511	Cell Signaling Technol-ogy, Frankfurt, Germany
anti-β-Actin	1:2000	4970	Cell Signaling Technology, Frankfurt, Germany
anti-CPN60	1:1000	sc-1053	Santa Cruz Biotechnology, Heidelberg, Germany
anti-P-eIF2α	1:1000	7921	Cell Signaling Technol-ogy, Frankfurt, Germany
anti-PKR	1:1000	sc-366777	Santa Cruz Biotechnology, Heidelberg, Germany
anti-P-ReIA	1:500	3039	Cell Signaling Technology, Frankfurt, Germany
anti-GRP78	1:4000	G9043	Sigma-Aldrich, Taufkirchen, Germany
anti-cleaved Caspase3	1:1000	9661	Cell Signaling Technology, Frankfurt, Germany

**Table 5. List of secondary antibodies used in Western blotting**

antibody	dilution	ID	company
anti-sheep	1:2000	----	Jackson ImmunoResearch, Hamburg, Germany
anti-rabbit	1:4000	----	Dianova, Hamburg, Germany
anti-goat	1:2000	----	Dianova, Hamburg, Germany

### Protein dephosphorylation

Cells were lysed in native cell lysis buffer (#9803, Cell Signaling Technology, Frankfurt, Germany) supplemented with 1mM PMSF. Approximate protein concentration was determined by Bradford protein assay. For dephosphorylation, 15 µg of native protein was treated with alkaline phosphatase (AP) for 15, 30, and 60 min, and with and without AP for 90 min following the manufacturer's instructions (New England Biolabs, Frankfurt, Germany).

## 3.4 Histological methods

### Histology and tissue staining

Freshly isolated intestinal tissue was fixed in 4% neutral buffered formalin for one to two days, dehydrated through a series of graded alcohol and xylene and embedded in paraffin (Leica Microsystems GmbH, Nussloch, Germany). Hematoxylin & eosin (H&E) staining and alcian blue staining were performed on 5 µm-thick tissue sections (Leica Microsystems GmbH, Nussloch, Germany) by using standard protocols. For morphological analysis, villus height, crypt depth, total epithelial area, and mucus area of 15-20 villi and/or crypts, respectively, was measured for each section using the LAS software (Leica Microsystems GmbH, Nussloch, Germany) and means were calculated. Mucus area is given as percentage of total epithelial area.

For immunohistochemistry (IHC), 5 µm-thick paraffin sections were applied onto poly-L-lysine coated slides and incubated overnight at 37°C. After rehydration, antigen retrieval was performed in 10 mM sodium citrate buffer (pH 6.0) by steaming sections in a microwave oven (900 Watt) for 23 min. Slides were rinsed with H<sub>2</sub>O and endogenous peroxidases were blocked for 10 min using 3% hydrogen peroxide (Fluka, Sigma-Aldrich, Taufkirchen, Germany). Tissue sections were washed twice in H<sub>2</sub>O for 5 min each and rinsed with PBST. Unless indicated otherwise, individual slides were washed 3 times with PBS for 5 min between each step. 5% BSA/PBS block was done for 30 min at RT. Primary antibodies against cleaved Caspase 3 (1:50, #9661, Cell Signaling Technology, Frankfurt, Germany), Ki-67

(1:100, ab15580, Abcam, Cambridge, UK), and CD19 (1:50, M-20, Santa Cruz Biotechnology, Heidelberg, Germany) were directly applied and incubated overnight at 4°C. Secondary anti-rabbit antibody (1:200, Dianova, Hamburg, Germany) was applied for 1 hour at RT and subsequently stained using 3.3'-diaminobenzidine solution (Sigma-Aldrich, Taufkirchen, Germany) with hematoxylin (Medite GmbH, Burgdorf, Germany) used as a counterstain. In addition, stainings for CD3 (1:300, RM-9107-S0, NeoMarkers/Lab Vision Corporation, CA, US), Ly6G (1:600, 551459, BD Pharmingen, Heidelberg, Germany), B220 (1:3000, 553084, BD Biosciences, Heidelberg, Germany), F4/80 (1:120, T-2006, BMA Biomedicals AG, Augst, Switzerland), and MHCII (1:500, NBP1-43312, Novus Biologicals, CO, US) were performed on 2 µm-thick tissue sections according to the staining protocol mentioned above. Notably, antigen retrieval for both B220 and CD3 as well as Ly6G was performed in EDTA buffer (1 mM EDTA, 0.05 % Tween 20, pH 8.0) by steaming sections in a microwave oven for 20 and 30 min, respectively. Antigen retrieval of tissue sections used for F4/80 and MHCII staining, respectively, were incubated with proteinase K for 10 min following standard protocol. Microscopic analyses were performed by using the LMD 6000 and the Leica Application Suite (LAS) software (Leica Microsystems GmbH, Nussloch, Germany) as well as by using the Olympus BX53 and Olympus cellSens Dimension 1.7 software (Olympus, Hamburg, Germany).

Immunofluorescence staining (IF) was performed following the protocol provided by Cell Signaling Technology. Primary antibodies (4°C, o/n) anti-E-Cadherin (1:100, ab76055, Abcam, Cambridge, UK), anti-Reg3β (1:50, AF5110, R&D Systems, Wiesbaden, Germany), anti-Ki-67 (100, ab15580, Abcam, Cambridge, UK), anti-CD19 (1:50, M-20, Santa Cruz Biotechnology, Heidelberg, Germany), and anti-Vimentin (1:50, #3932, Cell Signaling Technology, Frankfurt, Germany) were applied on paraffin sections, anti-HA-tag antibody was used for cryosections (1:4000, ab9110, Abcam, Cambridge, UK). Fluorescently labeled secondary antibodies anti-rabbit (A11012, Life Technologies, Karlsruhe, Germany), anti-mouse (A11001, Life Technologies, Karlsruhe, Germany), and anti-sheep (Jackson ImmunoResearch, Hamburg, Germany) were incubated for 1 hour at RT. Tissue sections were covered using mounting solution with DAPI (BIOZOL Diagnostica, Eching, Germany). TUNEL assay was performed using ApoBrdU DNA Fragmentation Assay Kit according to the manufacturer's instructions (K401-60, BioVision, Heidelberg, Germany). For positive controls, 5 µm-thick tissue sections were treated with DNaseI (*Macherey-Nagel GmbH & Co. KG*, Düren, Germany) for 15 min immediately after antigen retrieval. Further steps were done following the manufacturer's instructions. Microscopic analysis was performed by using the confocal laser scanning biological microscope FV10i (Olympus, Hamburg, Germany) and Volocity 3D Imaging Software (Perkin Elmer, Rodgau, Germany).

### Histopathological analysis

Histological scoring was performed on H&E stained tissue sections by blindly assessing the degree of inflammation as described by Katakura et al. <sup>205</sup>. Colonic tissue sections were scored for epithelial damage [0 = normal; 1 = hyperproliferation, irregular crypts, and goblet cell loss; 2 = mild to moderate crypt loss (10-50%); 3 = severe crypt loss (50-90%); 4 = complete crypt loss, surface epithelium intact; 5 = small- to medium-sized ulcer (<10 crypt widths); and 6 = large ulcer (≥10 crypt widths)] and infiltration of inflammatory cells [mucosa (0 = normal, 1 = mild, 2 = modest, 3 = severe), submucosa (0 = normal, 1 = mild to modest, 2 = severe), and muscle/serosa (0 = normal, 1 = moderate to severe)]. Calculated mean scores ranged from 0 (not inflamed) to 12 (massively inflamed).

### Laser capture microdissection

Freshly isolated intestinal tissue was immediately embedded in Tissue-Tek® (Weckert Labortechnik, Kitzingen, Germany). Serial frozen sections were cut into 10 µm size and applied onto RNase-free PET membrane slides (Leica Microsystems GmbH, Nussloch, Germany) followed by H&E staining using truncated standard protocol (70% ethanol for 1 min, DEPC water for 30 sec, hematoxylin for 20 sec, DEPC water for 30 sec, NH<sub>4</sub>OH (0.1%) for 30 sec, eosin (2%) for 10 sec, 96% ethanol for 30 sec, and 100% ethanol for 30 sec). A total area of 2,000,000 µm<sup>2</sup> was microdissected from epithelium, lamina propria, and muscularis, respectively, by using the UV laser-cutting system LMD 6000 and the LAS software (Leica Microsystems GmbH, Nussloch, Germany). Microdissected tissue was lysed in 50 µl RLT buffer supplemented with 1 mM mercaptoethanol and total RNA was prepared using RNeasy Micro Kit (Qiagen, Hilden, Germany) according to manufacturer's instructions.

## 3.5 Animal experimentation

All animal procedures were approved and performed according to institutional guidelines for the Bavarian Animal Care and Use Committee (AZ 55.2-1-54-2531-164-09, AZ 55.2-1-54-2532-160-12, AZ 55.2-1-54-2532-165-12).

### Generation of *Chop*<sup>Rosa26 flox/flox</sup> wild-type controls

C57BL/6N mice were used for knock-in mutagenesis to generate the *Chop*<sup>Rosa26 flox/flox</sup> strain that was purchased from Taconic. Therefore, a construct containing the CMV early enhancer/chicken β-actin (CAGGS) promoter and the coding sequence for murine CHOP protein with HA tagged to the C-terminus was introduced into Rosa26 locus. The promoter-associated floxed STOP sequence inhibits the expression of the transgene. Genotyping was performed by amplification of genomic DNA using primers *for\_5'-cacacgcacatccca-*

*aagc-3'*, *rev\_5'-ctggaacatcgtatgggtaagc-3'* for modified Rosa26 locus, and *for\_5'-catgtcttta-atctacctcgtatgg-3'*, *rev\_5'-ctcttcctcgtgatctgcaactcc-3'* for wild-type allele. Notably, construct generation was performed by Emanuel Berger (see "Generation of HA-tagged CHOP") who additionally organized, supervised, and managed the generation of transgenic mice.

### **Generation of homozygote *Chop*<sup>IEC Tg/Tg</sup> mouse model**

Homozygous *Chop*<sup>flox/flox</sup> females were mated with males expressing Cre recombinase under control of a 9kb regulatory region of mouse villin promoter (*vil-Cre*)<sup>206</sup>. The F1 offspring was genotyped for *vil-Cre* by amplification of genomic DNA using primers *for\_5'-caagcctggctcgacggcc-3'*, *rev\_5'-cgcgaacatcttcaggttct-3'* (Sigma-Aldrich, Taufkirchen, Germany). Mice were intercrossed avoiding double-positive *vil-Cre* mating pairs. The progeny of the F2 generation was genotyped for transgenic mice homozygous for *Chop-HA* with *vil-Cre* expression (*Chop*<sup>IEC Tg/Tg</sup>). *Chop*<sup>Rosa26 flox/flox</sup> and *Chop*<sup>IEC Tg/Tg</sup> mice were intercrossed, thus breeding for adequate wild-type controls (WT) and conditionally CHOP-HA overexpressing mice (TG). Mice were housed in specific pathogen free (SPF) facility and fed with standard diet V1124-300 (Ssniff, Soest, Germany) (Supplementary materials).

### **Isolation of intestinal epithelial cells**

The dissected intestine was inverted, rinsed twice with cold PBS, and placed in ice-cold DMEM with 10% FCS and 1 mM DTT (all from Life Technologies, Karlsruhe, Germany). After vigorous shaking for 1 min, the intestine was incubated for 20 min at 37°C with shaking (180 rpm). After vortexing for 1 min, the intestinal tissue was transferred into PBS containing 1.5 mM EDTA (Life Technologies, Karlsruhe, Germany) for further incubation on a shaker (10 min, 37°C, 180 rpm). Meanwhile, the first fraction was centrifuged for 5 min. Centrifugation steps were continuously performed at 300g and 4°C unless otherwise mentioned. The cell pellet was resuspended in 5 ml of fresh DMEM supplemented with 10% FCS and stored on ice. After vortexing for 1 min, the intestine was removed from PBS/EDTA solution and the cell suspension was centrifuged for 5 min. The cell pellet was pooled with former isolated IECs and purified by centrifugation through a 20/40 discontinuous Percoll gradient (GE, Healthcare, Uppsala, Sweden) for 30 min at 600g. IECs were resuspended in 1 ml of fresh DMEM with 10% FCS, separated in two volumes and pelleted for 5 min. The cell pellets were lysed in RA1 buffer for RNA extraction (*Macherey-Nagel GmbH & Co. KG*, Düren, Germany) and protein lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 2% CHAPS, 1% DTT (all from Roth, Karlsruhe, Germany), and protease inhibitor (Roche Diagnostics, Mannheim, Germany).

### **Isolation of small intestinal epithelial cells from villus tip to the crypt**

Dissected intestine was inverted, rinsed twice in 6 ml of cold PBS, and incubated in citrate buffer containing 96 mM NaCl, 1.5 mM KCl, 27 mM sodium citrate, 8 mM KH<sub>2</sub>PO<sub>4</sub>, 5.6 mM Na<sub>2</sub>HPO<sub>4</sub>, pH 7.3 (all from Roth, Karlsruhe, Germany) for 15 min at 37°C. Thereafter, tissue was incubated in PBS containing 1.5 mM EDTA, 0.5 mM DTT, 1 mg/ml BSA for 10, 10, 6, 5, 5, 9, 10, 15, 25, and 30 min at 37°C with shaking (180 rpm). Tissue was transferred into a new tube after each incubation step. Fractions were split in two volumes and immediately centrifuged at 300 g and 4°C. Cell pellets were lysed in RA1 buffer for RNA extraction (*Ma-cherey-Nagel GmbH & Co. KG, Düren, Germany*) and protein lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 2% CHAPS, 1% DTT (all from Roth, Karlsruhe, Germany), and protease inhibitor (Roche Diagnostics, Mannheim, Germany). Fractions 1 and 2 are defined to contain IECs from villus tip. To detect fractions containing IECs from crypt region, fractions 3 to 10 were analyzed for Ki-67 and Hes1 mRNA expression.

### ***Citrobacter rodentium* infection**

Female mice with the age of 8-10 weeks were inoculated orally with 2x10<sup>9</sup> colony-forming units (CFU) of *Citrobacter rodentium* ICC169 as previously described<sup>207</sup>. Changes in body weight, clinical condition of mice and bacterial load of RF-*C. rodentium* in fecal pellets were monitored every 2-3 days. Mice were sacrificed by cervical dislocation. Both colon weight and length was determined to express colonic weight/length ratio in milligram (mg) per millimeter (mg). Whole colonic tissue was fixed in 4% neutral buffered formalin for paraffin embedding. Alcian blue staining was performed and crypt depth, total epithelial area, and mucus area was assessed in distal colon using the LAS software (Leica Microsystems GmbH, Nussloch, Germany) as described in Histological methods. Mucus area was calculated as percentage of total epithelial area.

### **DSS-induced colitis**

2% DSS solution was prepared in a total volume of 2l (~ 150 ml per mouse) one week before starting the experiment. 40 g of DSS (MW 36,000-50,000, MP Biomedicals, Eschwege, Germany) was solved in 2l veH<sub>2</sub>O subsequently followed by sterile filtration. Solution was stored at 4°C. *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls (n = 5-6 per group) with an age of 12 weeks received 2% (w/v) DSS ad libitum for 3 and 7 days, respectively. Examination of epithelial repair in experimental colitis was performed providing 2% (w/v) DSS ad libitum for 5 days followed by a period of 5 days for recovery (n = 6 per group). Body weight was daily monitored and disease activity was assessed as further described in Animal experimentation. Mice were sacrificed by CO<sub>2</sub>. Spleen weight was determined to ex-

press spleen/body weight ratio and colon length and weight was assessed to calculate colonic weight/length ratio. The colon was opened longitudinally and carefully cut into two pieces. One half was used for IEC isolation and the other one was fixed in 4% neutral buffered formalin for paraffin embedding.

### Determination of disease activity index

The disease activity index (DAI) was assessed according to the scoring criteria as described in Murthy et al. <sup>208</sup>. Scores of body weight changes (0-4), stool consistency (0-4), and rectal bleeding (0-4) were calculated to a total score (0-12) and presented as sum  $\pm$ SD (Table 6).

**Table 6. Scoring criteria for disease activity index**

score	weight loss (%)	stool consistency*	rectal bleeding
0	None	normal	negative
1	1-5		
2	6-10	loose	gross bleeding
3	11-15		gross bleeding >1d
4	>15	diarrhea	gross bleeding >2d

\* normal = well formed pellets; loose = pasty stool, but clean anus; diarrhea = liquid stool that sticks to the anus

### *In vivo* wound healing assay

Colonic mucosal lesions with a diameter of 800  $\mu$ m were induced in transgenic mice and wild-type controls (n = 6 per group) as previously described <sup>209</sup>. Wound healing was monitored by video colonoscopy (KARL STORZ GmbH & Co.KG, Tuttlingen, Germany) on days 0, 1, 2, 3, and 5 and assessed by calculating wound size relative to original wound diameter. Mice were sacrificed by cervical dislocation at days 3 and 5 (n = 3 per group and day) and colonic tissue containing wound region was fixed in 4% neutral buffered formalin for paraffin embedding.

### *In vivo* BrdU labeling

*Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls with an age of 12 weeks were intraperitoneal-injected with BrdU labeling reagent following the manufacturer's instructions (Life Technologies, Karlsruhe, Germany). Mice (n = 5) were sacrificed on days 1 and 3 post injection by cervical dislocation. Intestinal tissue was fixed in 4% neutral buffered formalin for paraffin embedding. Immunohistological detection of BrdU-positive cells was performed by using the BrdU In-situ Detection Kit following the manufacturer's instructions (BD Biosciences,

Heidelberg, Germany). IHC double staining for BrdU and Ki-67 was performed following the manufacturer's instructions. Ki-67 positive cells were detected by using HRP-Green Solution Set (2 components) (life sciences GmbH & Co.KG, Bremerhaven, Germany).

### **3.6 Statistical analysis**

Statistical computations were performed by using SigmaPlot 11.0 (Systat software, Erkrath, Germany). Statistical significance was assessed by Student's t-test, non-parametric rank-sum test, and two-way ANOVA (TWA) with genotype and DSS treatment as main factors followed by Holm-Sidak test.  $P < .05$ ,  $P < .01$ , and  $P < .001$  was considered statistically significant.

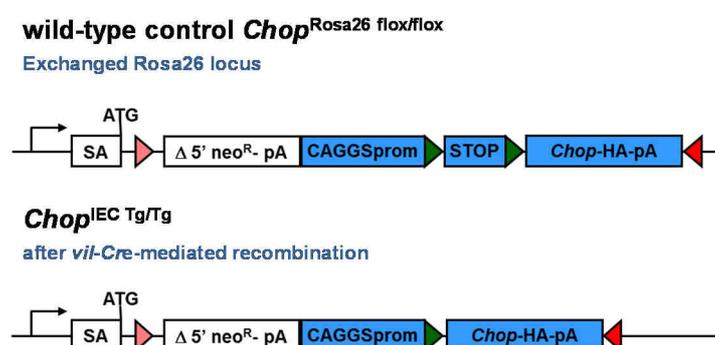

## 4. Results

### 4.1 Basic characterization of *Chop*<sup>IEC Tg/Tg</sup> mice

#### 4.1.1 Generation of new mouse model *Chop*<sup>IEC Tg/Tg</sup>

Transgenic mice that reveal high expression of HA-tagged CHOP protein restricted to the intestinal epithelial layer were generated by crossbreeding female wild-type controls *Chop*<sup>Rosa26 flox/flox</sup> with males expressing villin promoter-driven Cre recombinase (Figure 12)

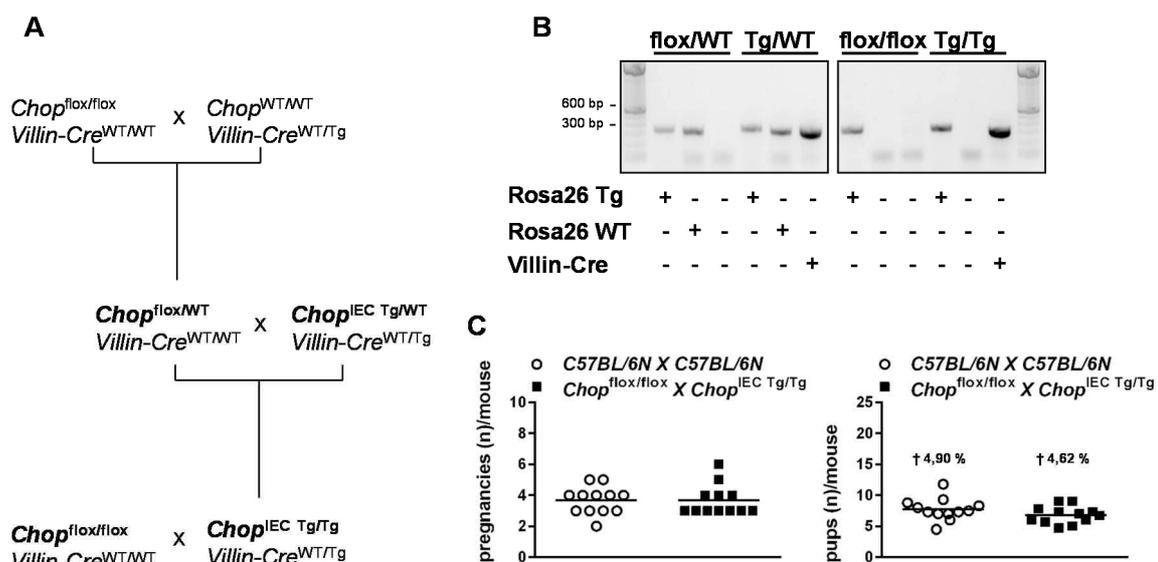

206

**Figure 12. Generation of new mouse model *Chop*<sup>IEC Tg/Tg</sup>.**

Wild-type controls *Chop*<sup>Rosa26 flox/flox</sup> were mated with Villin-Cre positive mice. Cre recombinase-mediated removal of promoter-associated floxed STOP sequence resulted in CAGGS promoter-driven high expression of the HA-tagged transgene CHOP-HA.

Homozygote *Chop*<sup>IEC Tg/Tg</sup> mice were generated following the breeding scheme shown in Figure 13. Genotyping was performed by using primer pairs for Villin-Cre and Rosa26 locus, respectively and offspring were intercrossed avoiding double-positive *vii*-Cre mating pairs. Animals used in experiments derived from breeding of homozygote *Chop*<sup>Rosa26 flox/flox</sup> and *Chop*<sup>IEC Tg/Tg</sup> mice with *Chop*<sup>Rosa26 flox/flox</sup> mice as adequate wild-type controls. The analysis of numbers of pregnancies and pups per mouse, respectively, indicated that genetic modification of mice did not affect breeding capacity when compared to C57BL/6N mice.

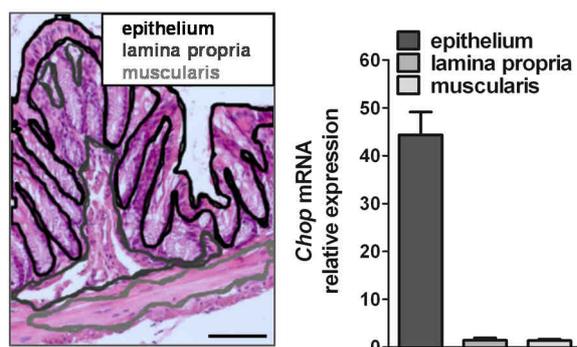

**Figure 13. Breeding scheme for  $Chop^{IEC Tg/Tg}$  mice and adequate wild-type controls.**

(A) Breeding scheme for the generation of homozygote transgenic mice and adequate wild-type controls. Wild-type controls  $Chop^{Rosa 26 flox/flox}$  are referred as  $Chop^{flox/flox}$  (B) Genetic background of progenies was determined by genotyping for both modification of Rosa26 locus and presence of *vil-Cre*. Mice were selected for following breeding avoiding double-positive *vil-Cre* mating pairs. (C) Analysis of breeding capacity for homozygote transgenic mice and adequate C57BL/6N wild-type controls. Number of pregnancies and litter size of mating pairs ( $n = 12$ ) were assessed over 6 month of breeding. Data are plotted as means. Lethality was assessed calculating numbers of death pups as percentage to total numbers of progenies.

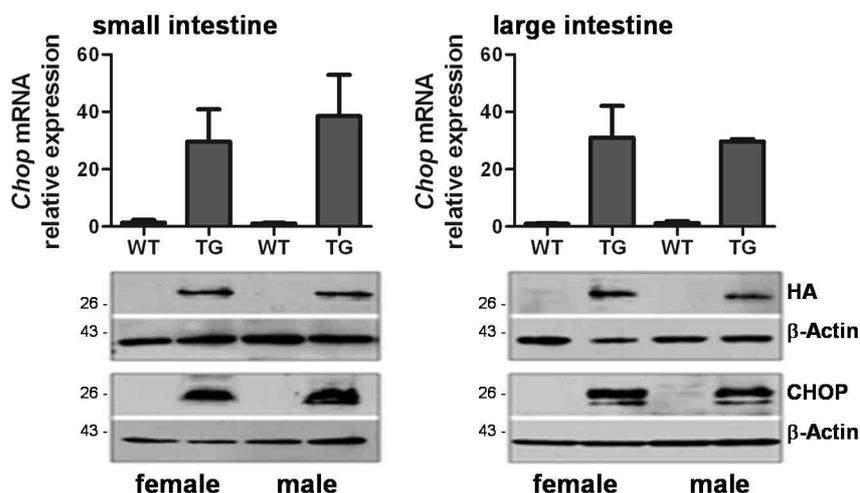

#### 4.1.2 Transgenic mice reveal high CHOP expression in intestinal epithelial cells

IEC-specific expression of transgenic CHOP with HA-tag fused to the C-terminus was shown by determining mRNA expression of Chop in cell isolates derived from lasermicro-dissected intestinal epithelium, lamina propria, and muscularis of transgenic mice and wild-type controls (Figure 14). Transgenic mice displayed high expression of Chop-HA on mRNA and protein level in the intestinal epithelium (Figure 15). Regarding qPCR analysis using IEC isolates ( $n = 5$ ) from small and large intestine, respectively, Chop-HA mRNA expression revealed 18- to 52-fold increase of transgenic Chop over endogenous Chop. Since transgenic CHOP protein is HA-tagged, both antibodies anti-CHOP and anti-HA were used in Western blot analysis.

**Figure 14. Analysis of intestinal epithelial cell-restricted mRNA expression of Chop-HA.**

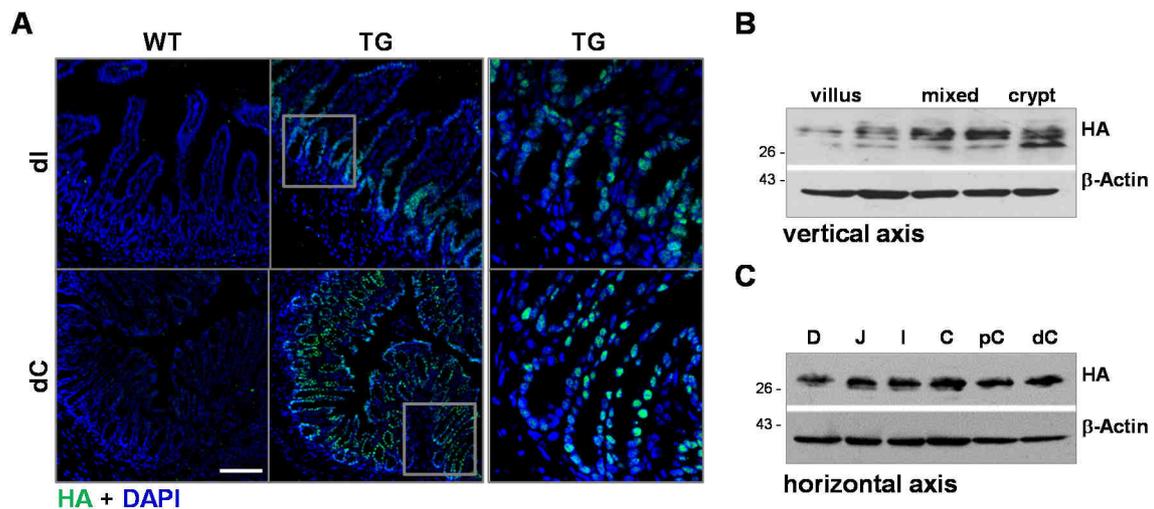

Tissue-specific mRNA expression of transgenic Chop was assessed by qPCR using isolates of microdissected cells derived from the intestinal epithelium, lamina propria, and muscularis of *Chop*<sup>IEC</sup><sub>Tg/Tg</sub> mice and wild-type controls (n = 3). Scale bar represents 100  $\mu$ m.

**Figure 15. Transgene expression in IEC isolates from small and large intestine of *Chop*<sup>IEC</sup><sub>Tg/Tg</sub> mice and wild-type controls.**

IECs were isolated from small and large intestine of 12 week old transgenic mice and wild-type controls (n = 3). Chop mRNA was determined by qPCR using intron-spanning primer pair. Data are plotted as means  $\pm$  SD. Pooled protein lysates were analyzed by Western blotting applying antibodies against CHOP protein and HA-tag.

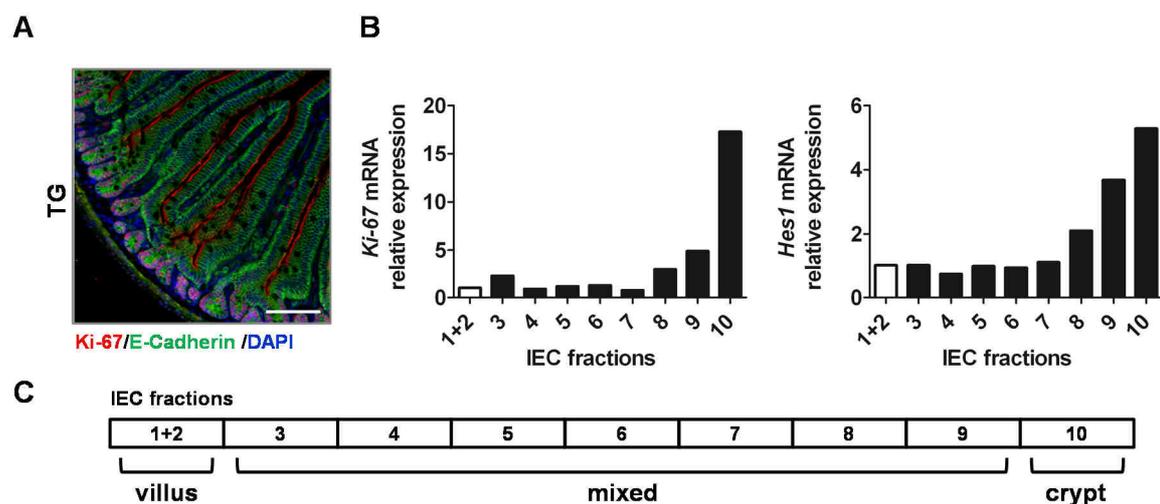

*Chop*<sup>IEC Tg/Tg</sup> mice showed high CHOP-HA protein expression in small and large intestine, respectively. Detected protein bands differ in molecular weight from ~26 to ~30 kDa, suggesting transgenic CHOP-HA to be post-translationally modified. The transgene is broadly expressed on both vertical and horizontal axis of the intestine (Figure 16). Immunofluorescence staining of colonic tissue sections indicated nuclear translocation of the HA-tagged transgene. Analysis of CHOP-HA protein expression along the intestine was performed by Western blotting using IEC isolates from the distinct intestinal sections.

**Figure 16. Expression of CHOP-HA on vertical and horizontal axis of the intestine.**

(A) Transgene expression was analyzed on 5  $\mu$ m-thick colonic tissue section using anti-HA antibody. DAPI was applied for nuclear staining. Scale bar represents 100  $\mu$ m. (B) Jejunal IECs were isolated from villus tip to the crypt and Western blot analysis was performed by using anti-HA antibody. (C) Total IEC isolates from intestinal sections duodenum, jejunum, ileum, cecum, proximal colon, and distal colon were analyzed by Western blotting using anti-HA antibody. Western blot data (B, C) represent results of 3 independent experiments

Transgene expression along the vertical axis was determined by Western blot analysis using jejunal epithelial cells from the villus and the crypt region. Therefore, 10 fractions containing jejunal IECs isolated from villus tip to the crypt were analyzed by qPCR for crypt markers including Ki-67 and Hes1 (Figure 17).

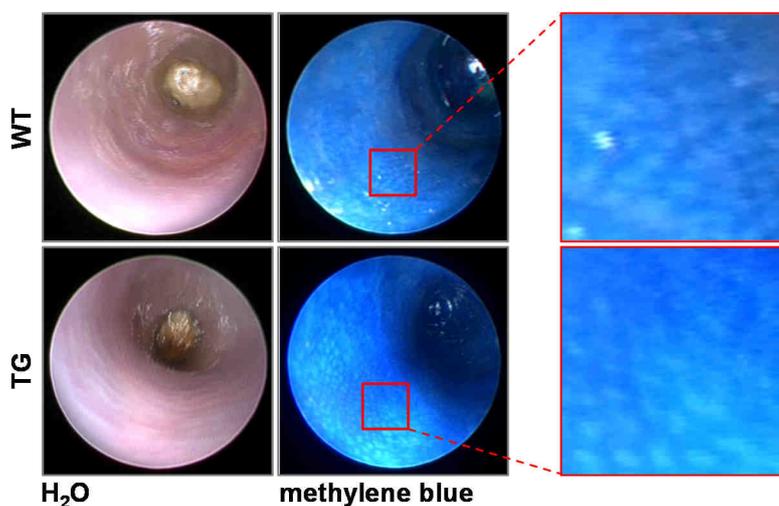

**Figure 17. Characterization of IEC fraction isolated from villus tip to the crypt.**

(A) IF of Ki-67 on jejunal tissue section of transgenic mice. Scale bar represents 100  $\mu$ m. Luminal red lining displays unspecific staining. (B) IEC fractions were analyzed for Ki-67 and Hes1 mRNA expression. Expression levels were calculated relative to fractions 1+2. (C) IEC fractions were characterized as fractions containing epithelial cells derived from villus tip and crypt region, respectively, according to the results obtained from qPCR for Ki-67 and Hes1 mRNA expression

Both Ki-67 and Hes1 mRNA expression was enhanced in fractions 8 to 10 with highest expression levels in fraction 10. With regard to jejunal tissue sections stained against Ki-67, proliferative cells could be specifically detected in crypt regions. Accordingly, fraction 10 has been defined to contain IECs derived from crypts, while epithelial cells isolated from villus tip have been regarded in fractions 1 and 2. Fractions 3 to 9 have been considered as mixed cell population. Taken together, *Chop*<sup>IEC Tg/Tg</sup> mice show high expression levels of nuclear located transgenic CHOP that is broadly expressed in IECs along the vertical and horizontal axis of the intestine.

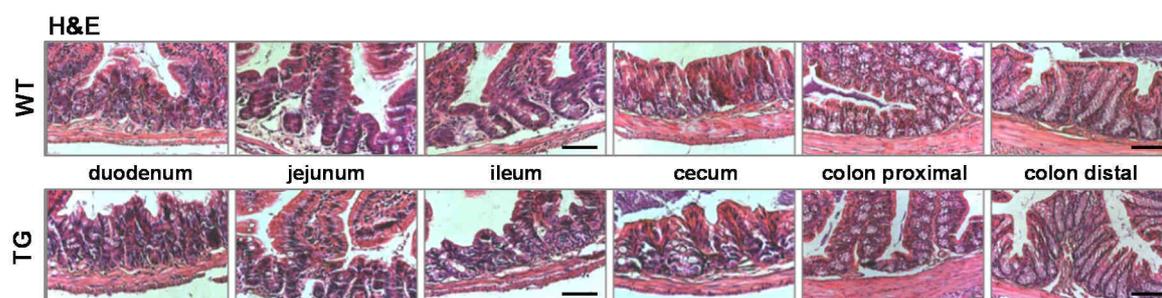

#### 4.1.3 *Chop*<sup>IEC Tg/Tg</sup> mice do not spontaneously develop intestinal inflammation

12 weeks old *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls were examined by chromoendoscopy using methylene blue for mucosal tissue staining. Following the colonoscopic evaluation, *Chop*<sup>IEC Tg/Tg</sup> mice appeared disease-free (Figure 18), which could further be confirmed at the histological level regarding histopathological parameters, such as crypt loss and inflammatory cell infiltration (Figure 19).

**Figure 18. Chromoendoscopic evaluation of *Chop*<sup>IEC Tg/Tg</sup> mice.**

Colonoscopy was performed in transgenic mice and controls before and after methylene blue was instilled into the colon. Colonic mucosa was evaluated for vascular structures, colonic crypt structures, and changes in mucus production.

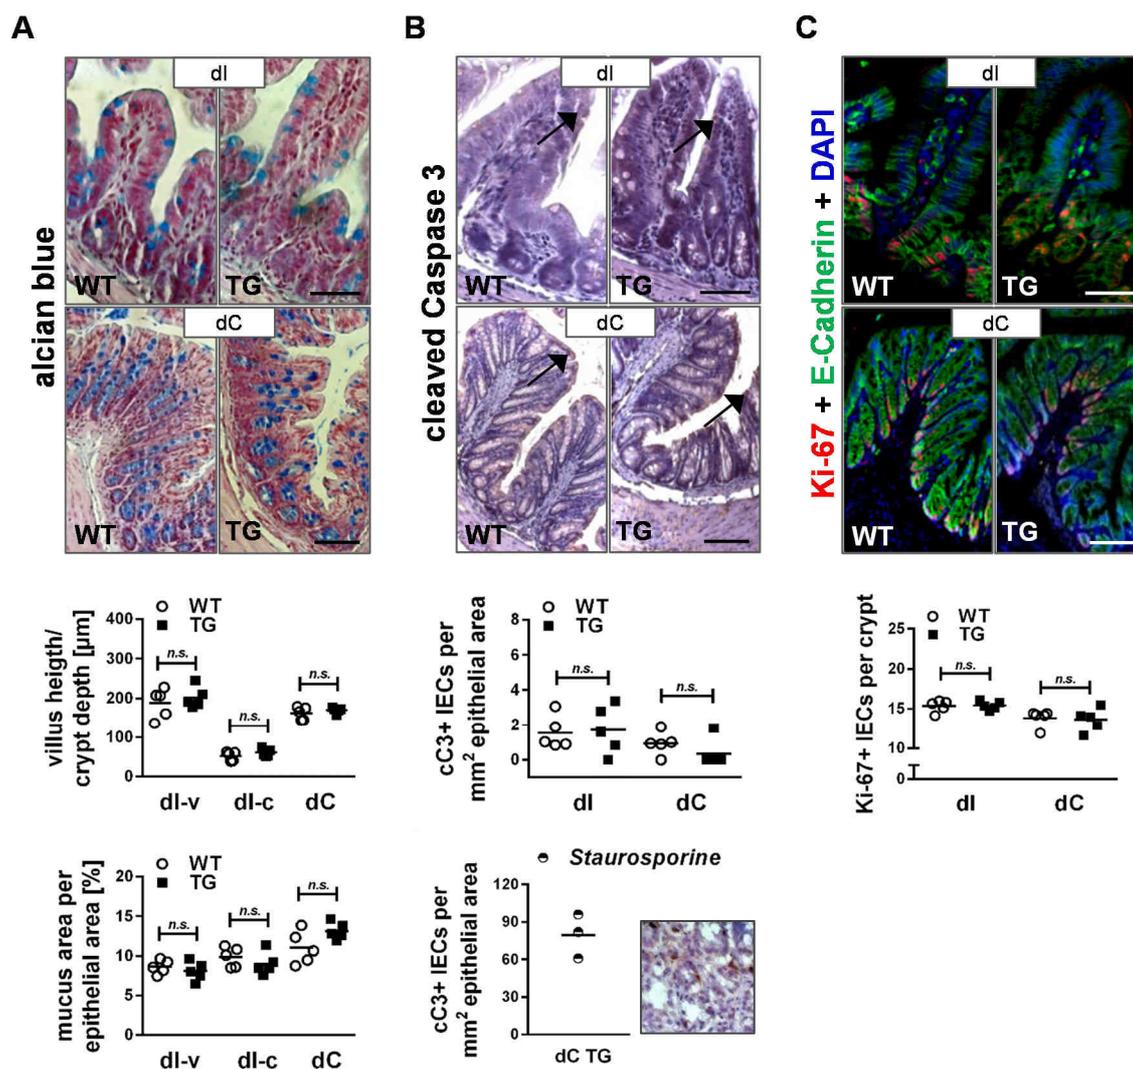

**Figure 19. H&E stained intestinal sections of *Chop*<sup>IEC Tg/Tg</sup> mice.**

Tissue sections from duodenum, jejunum, ileum, cecum, proximal colon, and distal colon of transgenic mice and wild-type controls were stained with hematoxylin and eosin. Scale bar represents 50  $\mu\text{m}$  for small intestinal sections, 100  $\mu\text{m}$  for cecum and colon

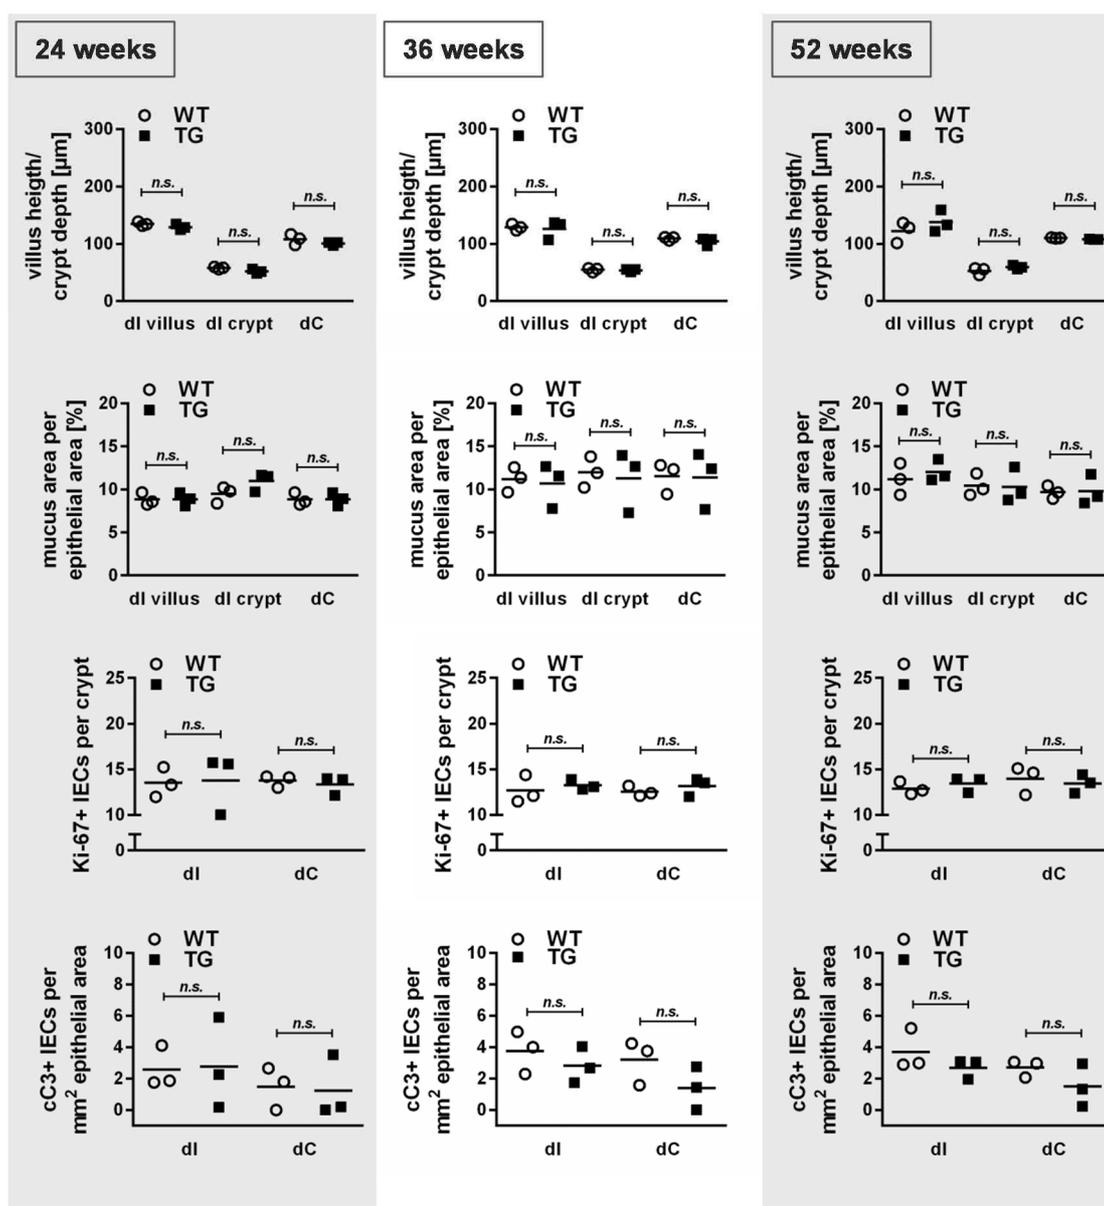

Furthermore, alcian blue-stained intestinal tissue sections from transgenic mice and wild-type controls with an age of 12, 24, 36, and 52 weeks were examined for morphological changes evaluating villus height, crypt depth, as well as mucus area. In addition, total numbers of apoptotic IECs per  $\text{mm}^2$  (cleaved Caspase 3) as well as proliferative cells per crypt (Ki-67) were assessed by IHC and IF (Figure 20 and Figure 21). As already indicated by the macroscopic observations, enhanced CHOP protein expression did not affect histometric characteristics, while numbers of both apoptotic and proliferative cells remained comparably to wild-type controls.

In conclusion, high CHOP protein expression does not lead to spontaneously developed inflammation of the intestine.

**Figure 20. Epithelial cell morphology of *Chop*<sup>IEC Tg/Tg</sup> mice with an age of 12 weeks.**

(A) Morphology of distal ileum (dl) and distal colon (dC) ( $n = 5$ ) was analyzed using 5  $\mu\text{m}$ -thick, alcian blue-stained tissue sections evaluating villus height, crypt depth, total epithelial area, and mucus area of 15-20 villi and/or crypts per animal, respectively, and means were calculated. Mucus area was assessed as percentage of total epithelial area. (B) Caspase 3 cleavage was considered as an apoptotic marker. Numbers of apoptotic cells were assessed in a total epithelial area of 1  $\text{mm}^2$  (see arrows). CC3 positive control staining was performed on 5  $\mu\text{m}$  tissue sections derived from distal colon of transgenic mice treated *ex vivo* with 1  $\mu\text{M}$  staurosporine for 2 h at 37° C. (C) Proliferative cells were detected by applying anti-Ki-67 antibody. For each tissue section, total numbers of Ki-67 positive cells were determined in 15-20 crypts and means were calculated. Data are plotted as numbers of proliferative cells per crypt. All data sets were analyzed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant. Scale bars represent 50  $\mu\text{m}$  (dl) and 100  $\mu\text{m}$  (dC).

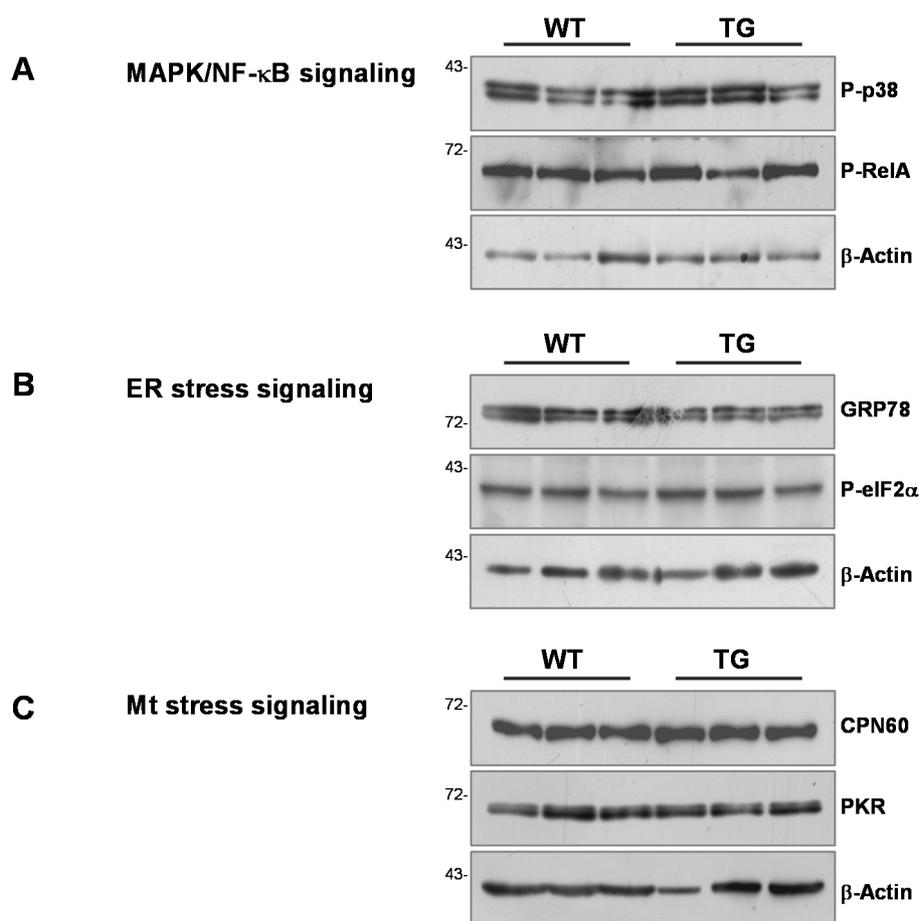

**Figure 21. IEC morphology of transgenic mice with an age of 24, 36, and 52 weeks.**

Analysis of epithelial cell morphology of 24, 36, and 52 weeks old transgenic mice and wild-type controls ( $n = 3$ ) was performed as mentioned for mice with an age of 12 weeks. All data sets were analyzed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant.

#### 4.1.4 Protein overexpression does not induce unspecific stress signaling

Transgene overexpressing animal models have been frequently criticized to induce cellular stress responses in an unspecific manner. Since CHOP-HA has been shown highly expressed in IECs, transgene-driven protein overload-dependent activation of stress-related signaling pathways was analyzed (Figure 22). Western blotting of both phosphorylated p38 MAP kinase and RelA, indicated that enhanced protein expression has no impact on activation of MAP kinase and NF- $\kappa$ B.

**Figure 22. Protein overload upon transgene overexpression does not cause activation of NF- $\kappa$ B, MAP kinase, ER stress signaling, and mitochondrial stress signaling.**

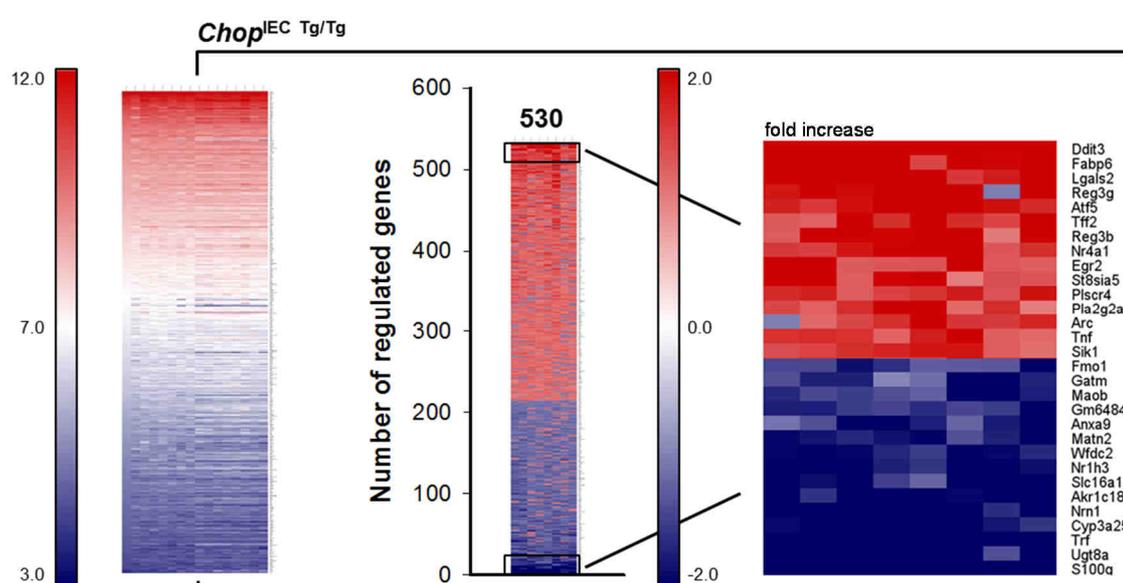

Protein overload-driven activation of stress-related signaling was examined by Western blotting using colonic IEC isolates. (A) Activation of NF- $\kappa$ B signaling was analyzed by using anti-P-RelA antibody. MAP kinase activation was determined applying anti-P-p38 antibody. (B) ER stress signaling was examined by using antibodies against GRP78 and P-eIF2 $\alpha$ . (C) Induction of mitochondrial stress was analyzed by using anti-CPN60 and anti-PKR antibodies. Shown data represent 3 independent experiments.

Furthermore, ER stress signaling (GRP78, p-eIF2 $\alpha$ ) as well as mitochondrial stress signaling (CPN60, PKR) remained unaffected by transgene overexpression. Taken together, elevated CHOP expression does not influence protein homeostasis in an unspecific manner.

## 4.2 Microarray analysis identifies CHOP-dependent changes in the inflammatory gene expression program

### 4.2.1 Enhanced CHOP protein expression sensitizes mice to stress-responsive gene regulation

To elucidate CHOP-driven transcriptional changes, gene expression profiling of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls (n = 8) was performed by whole genome microarray analysis using IEC isolates from colonic tissue. 530 genes were identified as significantly regulated ( $P < .05$ ) in transgenic mice compared to wild-type controls (Figure 23). 318 genes revealed an expression up to approximately 2-fold increase, whereas fold changes of most down-regulated genes appeared to be 2- to 5-fold decreased.

**Figure 23. Gene expression profiling of *Chop*<sup>IEC Tg/Tg</sup> mice indicates changes in the inflammatory gene program.**

Microarrays were performed by using freshly isolated total colonic IECs from female transgenic mice and wild-type controls with an age of 12 weeks (n = 8). Log<sub>2</sub>-based signal intensity ranged from 3 to 12. Expression data of 530 significantly regulated genes ( $P < .05$ ) are presented as fold-change over wild-type controls. Next, top 15 up- and down-regulated genes were illustrated.

Top 10 up- and down-regulated genes are shown in Table 7. As expected, *Ddit3* appears highest induced in *Chop*<sup>IEC Tg/Tg</sup> mice, while C/EBP signaling pathway was identified as one of the most significantly regulated pathways (Table 8).

**Table 7. Most highly regulated genes in *Chop*<sup>IEC Tg/Tg</sup> mice are shown as TOP 10 up-regulated and TOP 10 down-regulated genes, respectively.**

GO analysis reflecting short distance biological process child terms showed most significant gene enrichment affected by up-regulated genes, while changes in both metabolic process and localization additionally result from down-regulated gene sets (Table 9).

**Table 9. Significantly regulated child terms of the GO term biological process.** The shown child terms with significant enrichment of total regulated genes as well as up- and down-regulated genes, respectively, display main biological processes with a distance of 1 regarding the process tree. Analysis was performed by using the GeneRanker tool in the Genomatix Genome Analyzer.

GO-term	ID	total gene regulation			up-regulated	down-regulated
		genes observed	genes expected	P-value	P-value	P-value

biological regulation	GO:0065007	229	189	1,57E-04	7,70E-12	--

The four most enriched categories were further processed as followed. First, the biological process child terms cellular process, metabolic process, biological regulation, and response to stimulus were analyzed for shared gene sets (Figure 24A). Second, numbers of shared genes were calculated as percentage to total numbers of annotated genes (Figure 24B). As shown in Figure 24B, high enrichment of overlapping genes could be evaluated for the GO term response to stimulus (115 out of 177). Even though it remains unsolved whether CHOP directly impacts on the expression levels of these genes, it is worth to note that top regulated genes in the GO term response to stimulus reflected most of the highest enhanced/decreased genes in *Chop*<sup>IEC Tg/Tg</sup> mice (Table 10). With respect to GO terms annotated downstream of response to stimulus, highly significant changes in gene expression could be observed associated with inflammatory responses including the defense response and response to wounding (Table 11).

Taken together, these findings suggested that *Chop*<sup>IEC Tg/Tg</sup> mice exhibit changes in the gene expression program highly associated with IEC-driven microbial defense and response to wounding, but under normal conditions develop no spontaneous inflammation.

**Figure 24.** GO analysis regarding short distance biological process child terms revealed changes in the expression program associated with response to stimulus, death, and cell cycle.

Short distance biological process child terms indicating most enriched gene accumulation were analyzed for overlapping gene sets. (B) Total number of 115 overlapping genes was analyzed for significantly regulated biological process child terms. Herein, 10 most regulated overlapping genes associated with most significantly enriched categories were shown aside.

**Table 10.** Most highly regulated genes in *Chop*<sup>IEC Tg/Tg</sup> mice regarding GO term *response to stimulus* are shown as TOP 10 up-regulated and TOP 10 down-regulated genes, respectively.

#### 4.2.2 Validation of gene expression profiles by analyzing Reg3 $\beta$ expression

With regard to microarray data, highly significant changes in the expression of gene sets, such as enhanced expression of regenerating gene 3 (Reg3) family members *Reg3 $\alpha$*  (+1.2-fold), *Reg3 $\beta$*  (+1.9-fold), and *Reg3 $\gamma$*  (+2-fold) could be observed in the colonic epithelium of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice indicating a modulation of the gene expression program associated with microbial defense and response to wounding. Microarray-based up-regulation of Reg3 $\beta$  in colonic IECs has been validated by Western blotting and qPCR, while Reg3 $\beta$  expression is not affected in distal ileum of transgenic mice (Figure 25).

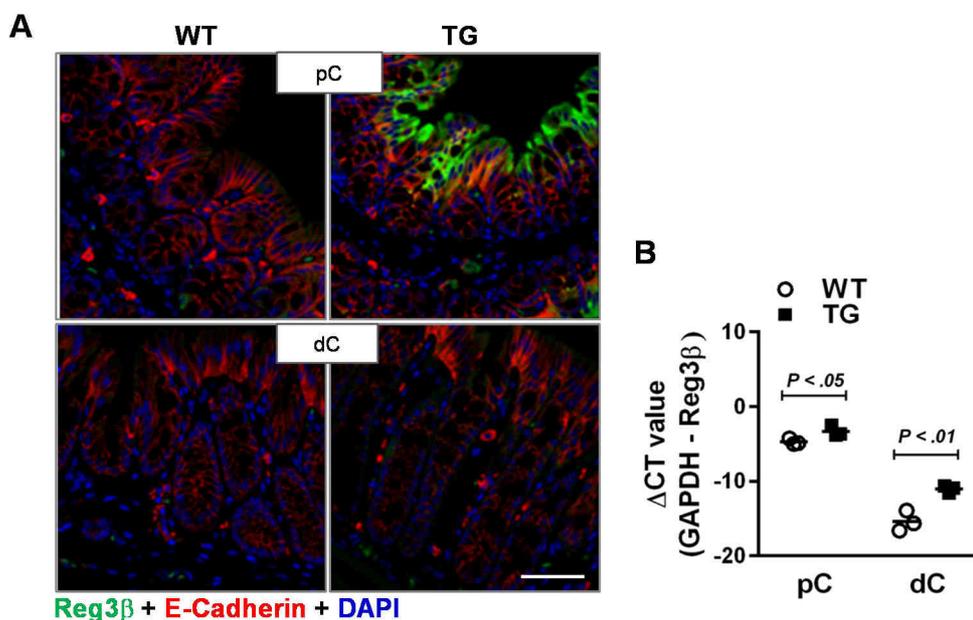

Notably, different mRNA expression levels of Reg3 $\beta$  could be observed in proximal and distal colonic epithelial cells (*proximal colon*:  $\Delta$ CT ~ -4.7,  $\Delta\Delta$ CT ~ 1.4; *distal colon*:  $\Delta$ CT ~ -15.4,  $\Delta\Delta$ CT ~ 4.3), which could be confirmed at the protein expression level regarding IF for Reg3 $\beta$  on tissue sections of proximal and distal colon (Figure 26).

In conclusion, these findings validated microarray-based up-regulation of Reg3 $\beta$  in IECs of *Chop*<sup>IEC Tg/Tg</sup> mice at the level of mRNA and protein expression. Notably, the expression of Reg3 $\beta$  is specifically up-regulated in colonic tissue, but not in epithelial cells of the small intestine.

**Figure 25. Reg3β expression in IECs of colon and distal ileum.**

(A) Reg3β expression was analyzed by Western blotting using colonic epithelial cell isolates from transgenic mice and wild-type controls ( $n = 3$ ). (B) mRNA expression of Reg3β in IECs isolates of distal ileum and colon from TG and WT mice ( $n = 3$ ). Statistical significance was assessed by Student's t-test.  $P < .05$  was considered statistically significant. (C) Reg3β expression in IECs of distal ileum from TG and WT mice, respectively. Scale bar represents 50  $\mu\text{m}$ .

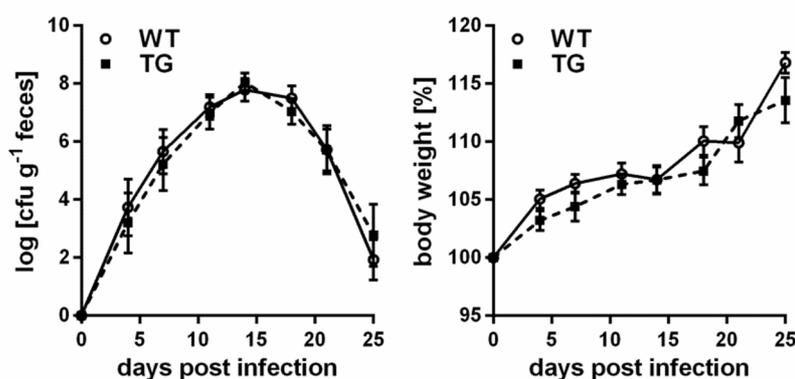

**Figure 26. Validation of microarray data through the analysis of Reg3β expression.**

(A) IF for Reg3β was performed on 5  $\mu\text{m}$  tissue sections of proximal and distal colon from transgenic mice and wild-type controls, respectively. Scale bar represents 50  $\mu\text{m}$ . (B) Reg3β expression was analyzed by qPCR using IECs derived from proximal and distal colon of  $Chop^{\text{IEC Tg/Tg}}$  mice and wild-type controls ( $n = 3$ ). Statistical significance was assessed by Student's t-test.  $P < .05$  was considered statistically significant.

### 4.3 IEC-specific CHOP overexpression does not affect infection with *Citrobacter rodentium*, but exacerbates DSS-induced colitis

#### 4.3.1 Enhanced CHOP protein expression does not affect colonization and clearance of *Citrobacter rodentium*

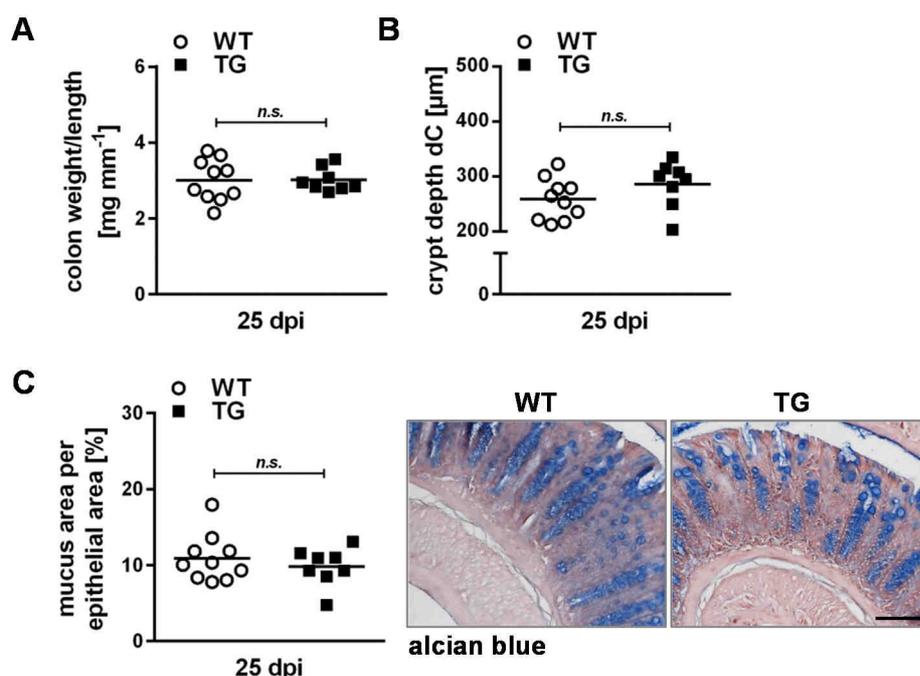

Infection of mice with the gram-negative, mouse-specific, enteric pathogen *C. rodentium* triggers colonic inflammation associated with Goblet cell loss and epithelial hyperplasia that serves as a study model for human enteric infection with the pathogens enteropathogenic *Escherichia coli* (*E. coli*) and enterohaemorrhagic *E. coli* <sup>210-212</sup>. Recently published data clearly demonstrated that changes in Reg3 $\beta$  expression affected the outcome of colitis mediated by the gram-negative pathogen *Salmonella enteritidis* <sup>213</sup>. Thus, *C. rodentium*-mediated colitis is considered as an adequate study model to investigate the effects of CHOP-driven changes in the microbial defense program associated with enhanced Reg3 $\beta$  expression. Based on the course of infection and body weight development, *C. rodentium*-induced colitis in *Chop*<sup>IEC Tg/Tg</sup> mice proceeded comparably to infected wild-type controls (Figure 27).

**Figure 27. *C. rodentium* infection of 8 weeks old *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls.**

Female transgenic mice (n = 8) and wild-type controls (n = 10) were orally infected with approximately  $2 \times 10^9$  CFU of *C. rodentium* ICC169. Fecal pellets were collected every 2-3 days and the course of infection was assessed by determining the bacterial load of *C. rodentium* in fecal pellets. *C. rodentium* counts are plotted as mean  $\pm$  SEM log<sub>10</sub> CFU per gram of feces. Body weight changes were determined every 2-3 days. Data are presented as mean  $\pm$  SEM.

Consistent with these data, similar progression of *C. rodentium* infection in transgenic mice and wild-type controls could be observed regarding colonic weight/length ratio as well as disease activity parameters, such as distal colonic crypt depth and mucus area (Figure 28).

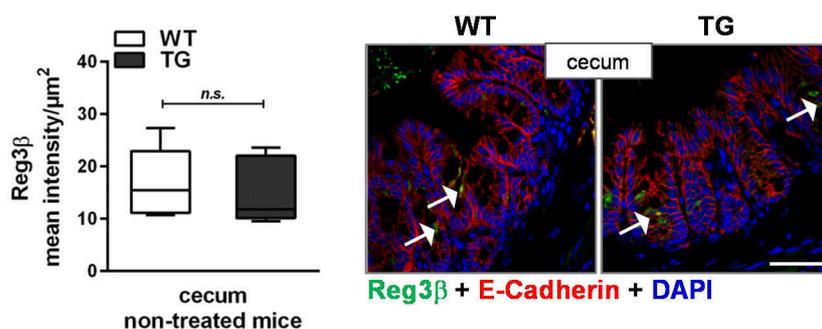

**Figure 28. Disease parameter in *C. rodentium* infection.**

(A) The macroscopic disease activity parameter colonic weight/length ratio in mg/mm was calculated for each mouse 25 days post infection (dpi). (B, C) 5  $\mu$ m tissue sections of paraffin-embedded colonic tissue were stained with alcian blue. Crypt length, total epithelial area, and mucus area was assessed in distal colon of each mouse. Mucus area is plotted as percentage of total epithelial area. Representative tissue sections of distal colon are shown, scale bar represents 200  $\mu$ m. Statistical significance was assessed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant.

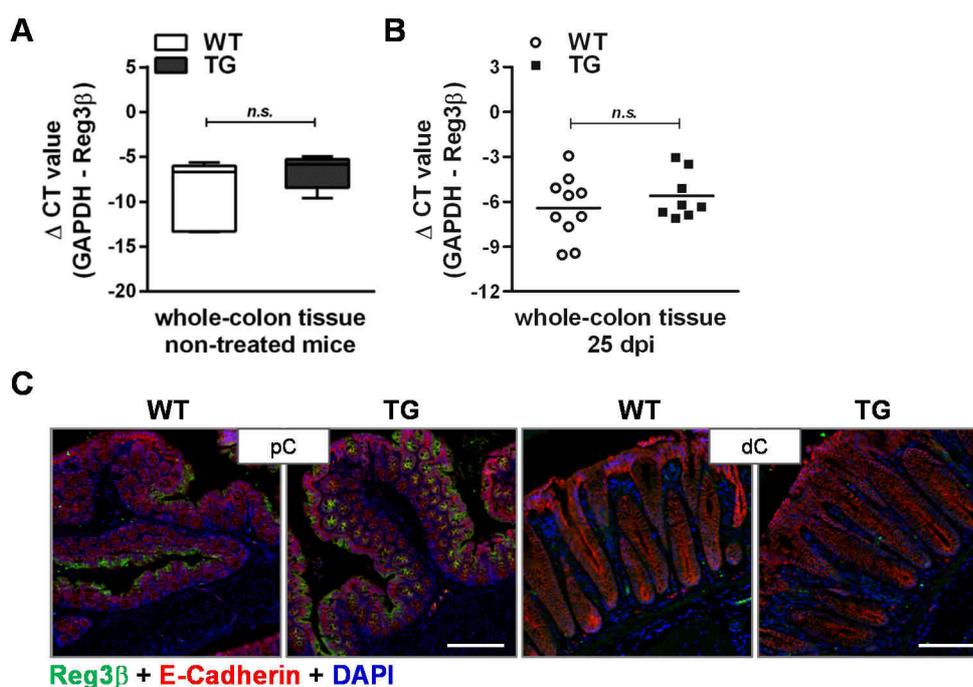

It is known that *C. rodentium* spreads to the distal colon shortly after cecal colonization<sup>214, 215</sup>. Since neither colonization nor clearance of *C. rodentium* was affected in transgenic mice, we addressed Reg3 $\beta$  expression in first, cecal tissue of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice, second colonic tissue of infected mice. Interestingly, disease-free transgenic mice showed unchanged expression of Reg3 $\beta$  when IEC-specific protein levels were compared to wild-type controls (Figure 29), while infected mice (WT and TG) clearly revealed elevated Reg3 $\beta$  expression during clearance of *C. rodentium* (Figure 30).

Taken together, these findings suggest that elevated Reg3 $\beta$  expression in colon of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice does not play an important role in colonization and clearance of *C. rodentium*.

**Figure 29. Reg3 $\beta$  expression in cecal tissue of *Chop1*<sup>EC Tg/Tg</sup> mice and wild-type controls.**

Immunofluorescence was performed on 5  $\mu$ m cecal tissue sections of disease-free transgenic mice and wild-type controls ( $n = 5$  per group) by using primary antibody against Reg3 $\beta$ . IECs were detected applying anti-E-Cadherin antibody, DAPI was used for nuclear staining. Scale bar represents 50  $\mu$ m. Reg3 $\beta$ -positive staining in IECs was quantified and mean intensity per  $\mu$ m<sup>2</sup> of epithelium is presented  $\pm$ SD. Statistical significance was assessed by Student's t-test,  $P < .05$  was considered statistically significant.

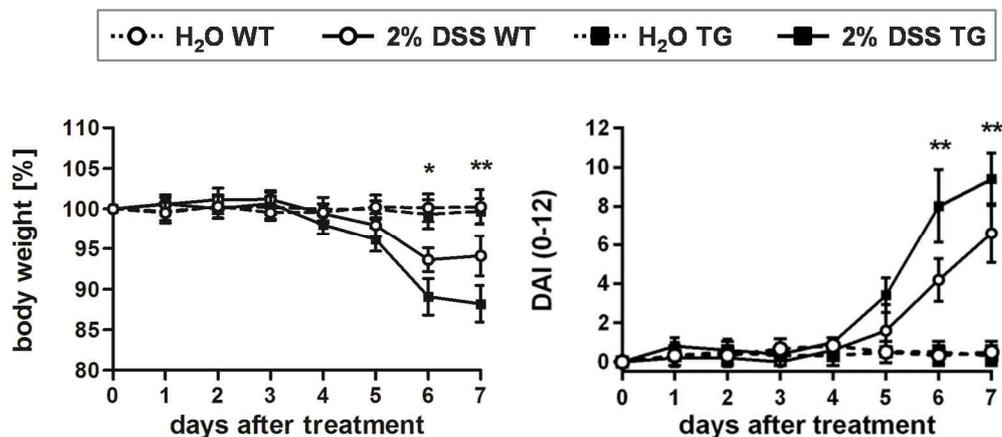

**Figure 30. Analysis of Reg3 $\beta$  expression in mice 25 days after *C. rodentium* infection.**

(A) Basal levels of Reg3 $\beta$  mRNA expression in whole-colon tissue were analyzed using pathogen-free female mice ( $n = 5$  per group). Data are plotted as  $\Delta$ CT  $\pm$ SD. (B) Reg3 $\beta$  mRNA levels of *C. rodentium*-infected mice were analyzed by using total RNA isolates of whole-colon tissue that was dissected 25 dpi. Data are presented as  $\Delta$ CT  $\pm$ SD. (C) IF for Reg3 $\beta$  was performed using 5  $\mu$ m-thick tissue sections from both proximal and distal colon of *Chop1*<sup>EC Tg/Tg</sup> mice and wild-type controls (25 dpi). Epithelial cells were stained using anti-E-Cadherin antibody. DAPI was used for nuclear staining. Scale bars represent 200  $\mu$ m (pC) for pC and 100  $\mu$ m (dC). Statistical significance for all data sets was assessed by Student's t-test,  $P < .05$  was considered statistically significant.

### 4.3.2 High CHOP protein expression aggravates susceptibility to DSS-induced colitis associated with delayed recovery

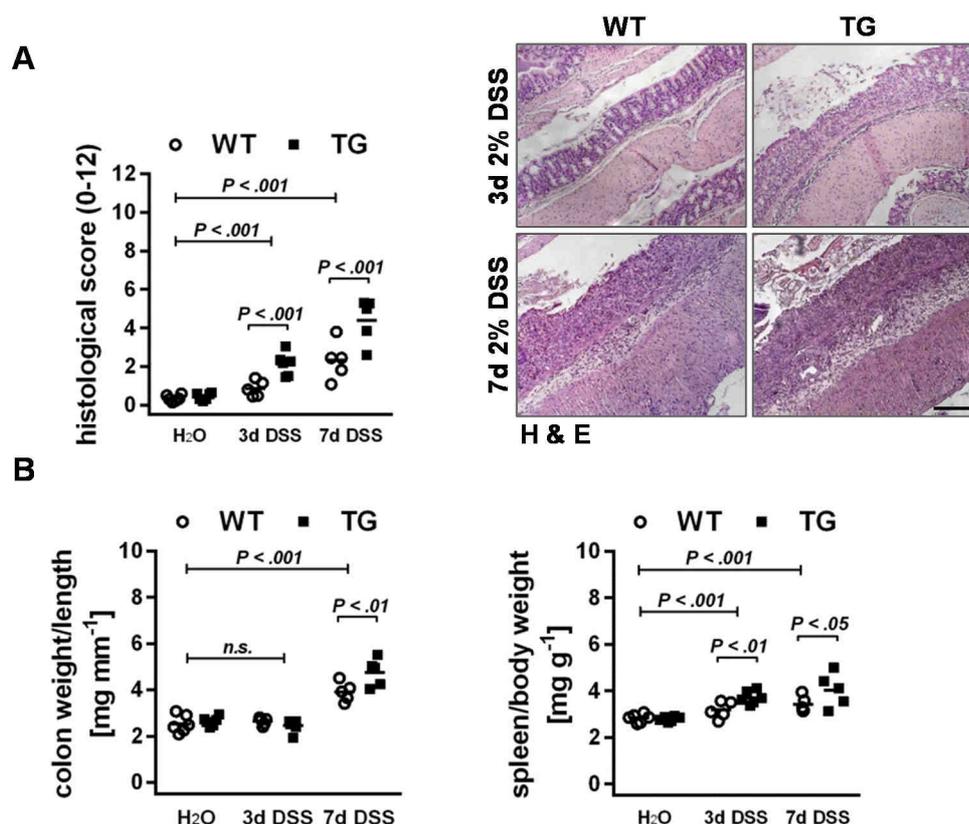

DSS-induced colitis is characterized by severe changes of the intestinal architecture and epithelial damage, such as hyperproliferation, goblet cell loss, crypt loss, and ulcer formation, as well as infiltration of inflammatory cells<sup>216, 217</sup>. Although the specific effects of DSS on intestinal tissue are still unclear, the DSS-induced colitis model is widely used to elucidate the impact of distinct genes of interest on inflammatory processes. To investigate whether an IEC-specific CHOP overexpression has an effect on the inflammatory phenotype in experimental colitis, 2% DSS was orally given with drinking water for 3 and 7 days, respectively. *Chop*<sup>IEC Tg/Tg</sup> mice showed significantly enhanced severity in DSS-induced colitis regarding body weight loss and changes in DAI after 7 days of DSS administration (Figure 31).

**Figure 31. *Chop*<sup>IEC Tg/Tg</sup> mice are more susceptible to DSS-induced colitis.**

Mice were given 2% of DSS for 7 days (n = 5), water was applied as negative control (n = 6). Body weight changes and DAI were monitored daily and percentage to initial body weight was assessed. Data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  (\*) and  $P < .01$  (\*\*) was considered statistically significant. Data were presented as means  $\pm$ SD.

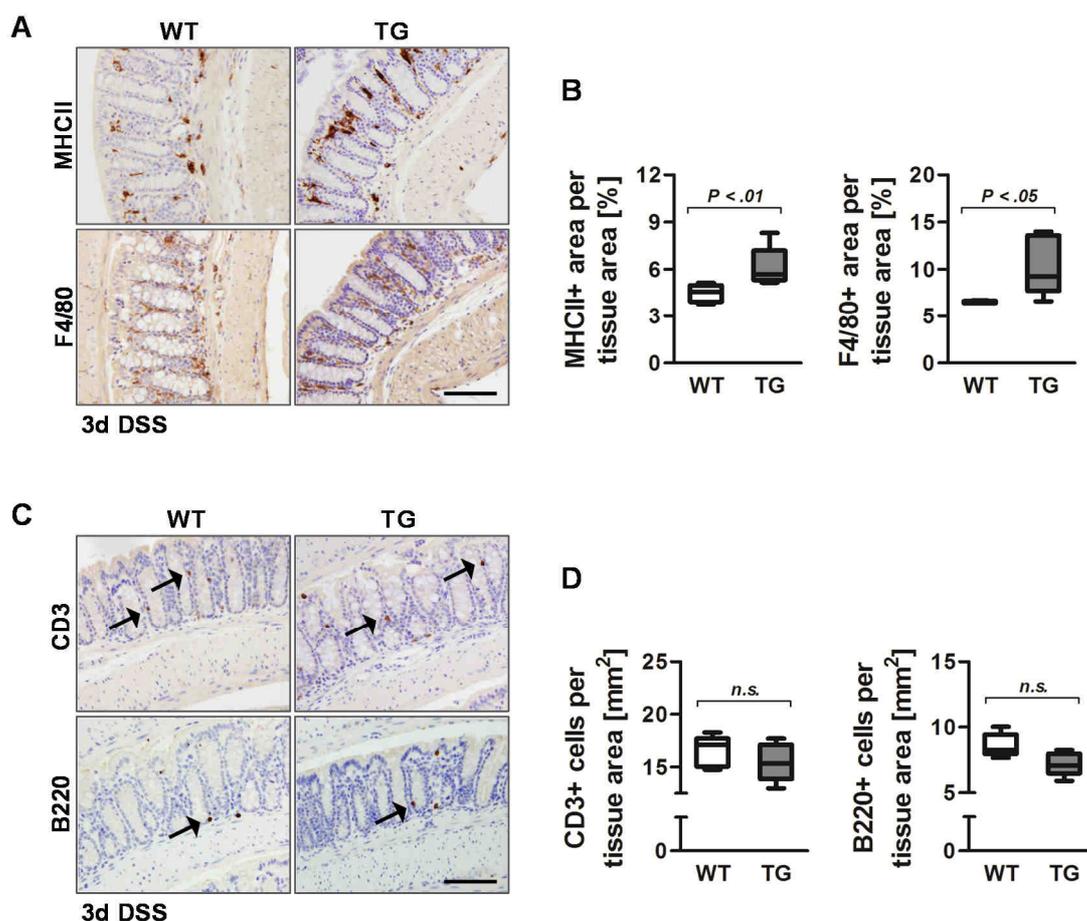

These data correlated with increased mucosal tissue damage in 3 and 7 days DSS-treated transgenic mice compared to wild-type controls (Figure 32A, Supplementary table 1). Similar effects were shown regarding the colonic weight/length ratio as well as the spleen/body weight ratio (Figure 32B).

**Figure 32. DSS-treated *Chop*<sup>IEC Tg/Tg</sup> mice reveal enhanced tissue pathology.**

(A) Histological scores of colonic tissue sections are presented from both 3 days (*Chop*<sup>IEC Tg/Tg</sup> mice  $n = 6$ , wild-type controls  $n = 5$ ) and 7 days DSS-treated mice ( $n = 5$ ) as well as water-treated controls ( $n = 6$ ). Representative H&E stained colonic tissue sections of DSS-treated mice are shown. Scale bar represents 200  $\mu\text{m}$ . Colonic weight/length ratio in mg/ml and spleen/body weight ratio in mg/g are shown in (B). All data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  was considered statistically significant. Significant differences are illustrated considering both genotype and treatment as well as genotype-dependent differences in one treatment group.

With regard to early inflammation, colonic tissue sections of 3 days DSS-treated mice were analyzed for immune cell infiltration. As shown in Figure 33, numbers of mucosa-infiltrating immune cells, including macrophages, are enhanced in *Chop*<sup>IEC Tg/Tg</sup> mice, while numbers of T cells (CD3), B cells (CD220, CD19), and neutrophils (Ly6g) remained unchanged when compared to wild-type controls.

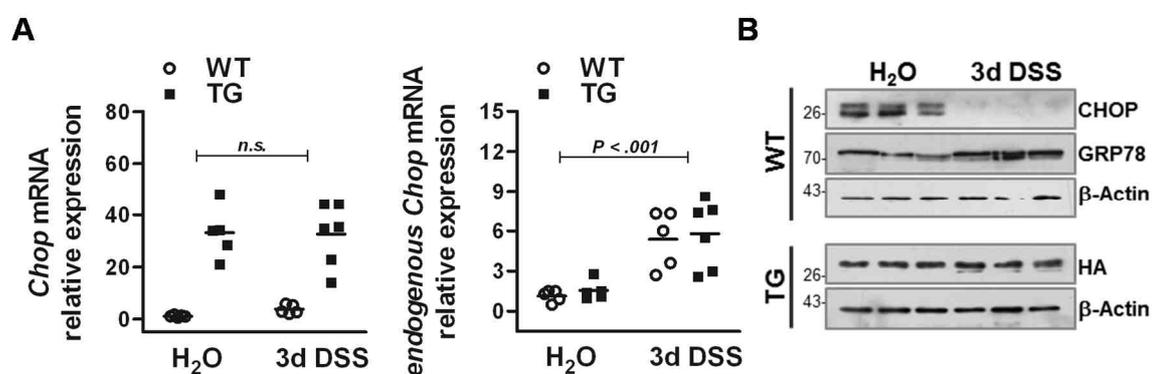

**Figure 33. Analysis of mucosa-infiltrating immune cells in 3 days DSS-treated mice.**

Colonic tissue sections of 3 days DSS-treated mice ( $n = 5-6$ ) were analyzed for immune cell infiltration performing IHC for MHCII and F4/80 (A, B) as well as CD3 and B220 (C, D). MHCII+ and F4/80+ area, respectively, was quantified and calculated as percentage to total tissue area. CD3+ and B220+ cells were counted in total tissue and assessed as numbers of CD3+ and B220+ cells, respectively, per mm<sup>2</sup> of total tissue area. Statistical significance was assessed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant.

To examine the early mechanisms of disease progression, colonic IEC were isolated from 3 days DSS-treated mice and water-treated controls, and analyzed for the expression of CHOP, GRP78 and CHOP target genes *Gadd34*, *Ero1 $\alpha$* , *Atf3*, *BIM*, *Trb3*, and *Bcl-2*. The expression of *Chop* mRNA was not significantly regulated upon DSS treatment using intron-spanning primer pair detecting both endogenous and transgenic *Chop*. Further analysis of *Chop* expression using primers specifically binding to the 5'-untranslated region of *Chop* revealed endogenous *Chop* mRNA expression 2.5- to 9-fold enhanced in DSS-treated mice compared to water-treated controls (Figure 34A). In contrast, endogenous CHOP protein expression was decreased, while GRP78 expression was induced in 3 days DSS-treated wild-type mice. Transgenic CHOP protein expression remained comparably regulated in DSS- and water-treated *Chop*<sup>IEC Tg/Tg</sup> mice (Figure 34B). Consistent with earlier observations,

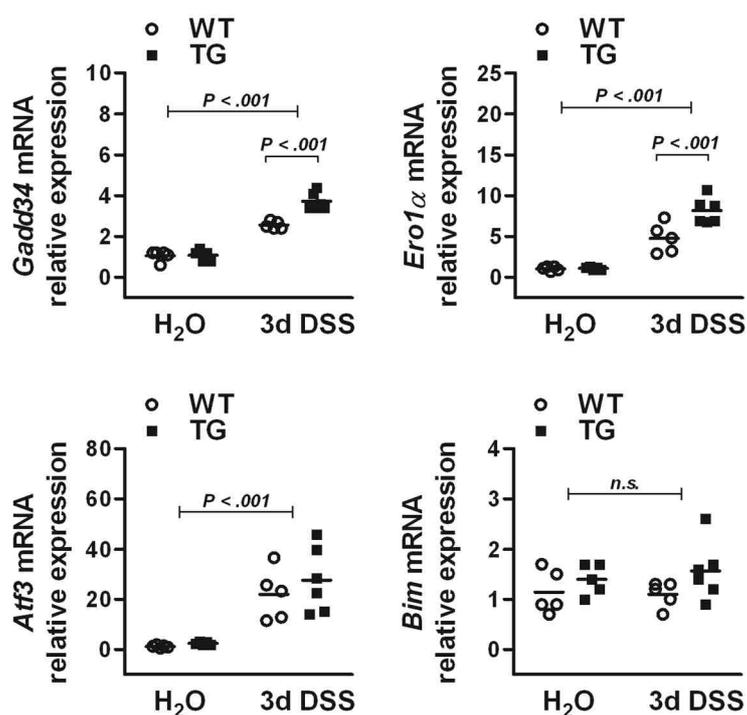

CHOP-HA bands differed in molecular weight from ~26 to ~30 kDa with CHOP-HA ~26 kDa slightly more pronounced in DSS-treated mice.

**Figure 34. Analysis of CHOP and transgene expression in 3 days DSS-treated mice.**

IECs were isolated from water-treated and 3d DSS-treated mice. (A) Expression of transgenic and endogenous Chop mRNA was detected by using intron-spanning primers, while endogenous Chop expression was specifically detected using primers binding to the 5'-untranslated region of Chop. Data were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  was considered statistically significant. (B) Protein expression of CHOP, transgenic CHOP, and GRP78 ( $n = 3$ ) was analyzed by Western blotting.  $\beta$ -Actin was used as loading control.

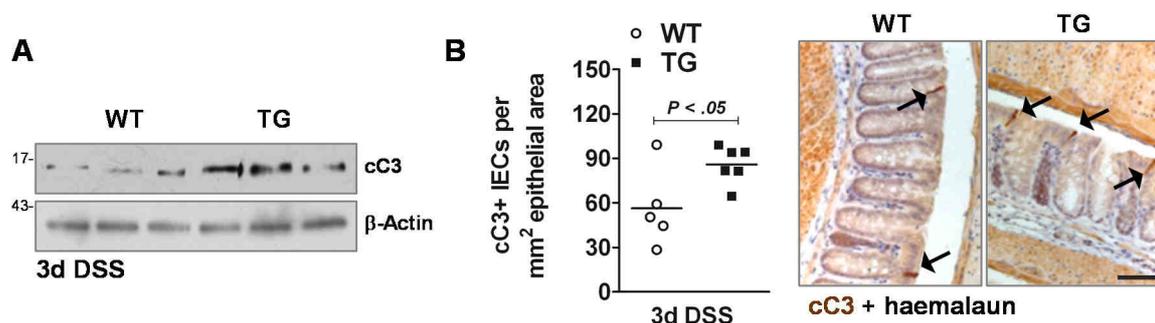

The analysis of CHOP target gene expression revealed significantly increased mRNA expression levels for *Gadd34*, *Ero1 $\alpha$*  and *Atf3* in DSS-treated mice with significant higher induction of both *Gadd34* and *Ero1 $\alpha$*  in DSS-treated transgenic mice (Figure 35). *Trb3* and *Bcl-2* could not be detected by qPCR.

**Figure 35. CHOP target gene expression in 3d DSS-treated mice.**

The expression of CHOP target genes Gadd34, Ero1 $\alpha$ , Atf3, and BIM was analyzed by qPCR using IEC isolates of 3d DSS-treated mice and water-treated controls (n = 5-6). All data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  was considered statistically significant. Significant differences are illustrated considering both genotype and treatment as well as genotype-dependent differences in one treatment group.

However, significantly enhanced pro-apoptotic signaling could be achieved for 3 days DSS-treated mice regarding the cleavage of Caspase 3, which was further increased in transgenic mice (Figure 36).

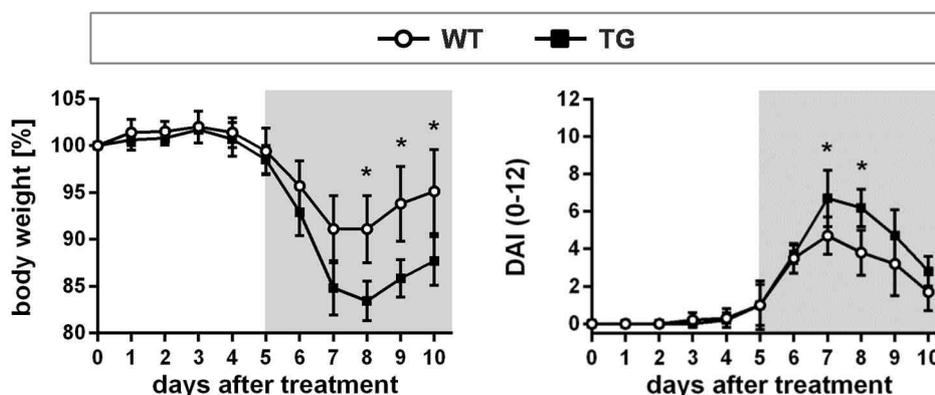

**Figure 36. DSS-treated transgenic mice show an increase of cleaved caspase 3.**

(A) Proapoptotic signaling was analyzed by performing Western blotting applying anti-cC3 antibody and anti- $\beta$ -Actin antibody as loading control. (B) IHC was performed on 5  $\mu$ m-thick colonic tissue sections of 3 days DSS-treated mice by using primary antibody against cC3. Numbers of cC3-positive IECs were assessed in a total epithelial area of 1 mm<sup>2</sup>. Statistical significance was assessed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant. Arrows in representative tissue sections indicate cC3-positive cells in WT and TG, scale bar represents 200  $\mu$ m.

In summary, these data demonstrate that high CHOP protein expression in IECs exacerbates acute inflammation in experimental colitis in transgenic mice associated with enhanced immune cell infiltration, induced expression of CHOP target genes *Gadd34* and *Ero1 $\alpha$* , respectively, and increased numbers of cC3-positive epithelial cells.

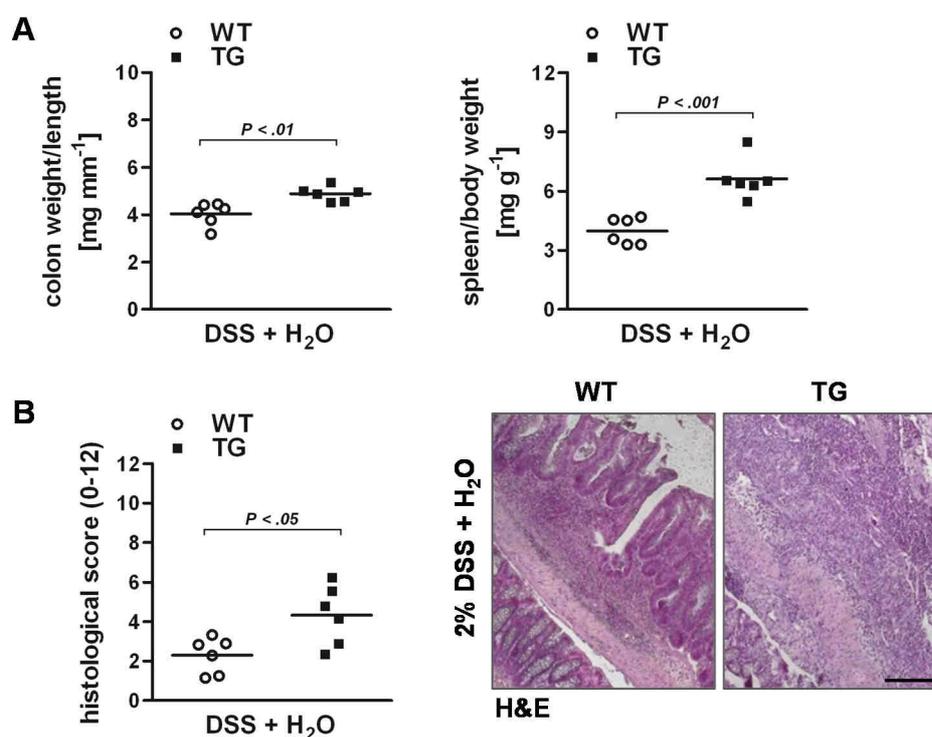

Most studies dealing with CHOP and CHOP-mediated signaling have been related to pro-apoptotic signaling. Meanwhile, a growing number of studies accumulated suggesting that CHOP protein might be mechanistically involved in the regulation of proliferation as well as cell differentiation<sup>168,194</sup>. To investigate whether IEC-specific CHOP protein is implicated in epithelial regeneration, mucosal healing was evaluated upon DSS-induced tissue damage. Therefore, 2% DSS was given for 5 days followed by a recovery period of 5 days. Transgenic mice were significantly retarded in their capacity to recover from DSS-induced colitis regarding the changes in body weight and DAI (Figure 37). This observation was further supported by significantly increased colonic weight/length ratio and spleen/body weight ratio, respectively (Figure 38A). In the context of epithelial regeneration, histological evaluation of affected tissue clearly indicated that disease severity was significantly associated with delayed mucosal repair in *Chop*<sup>IEC Tg/Tg</sup> mice (Figure 38B, Supplementary table 1).

**Figure 37. *Chop*<sup>IEC Tg/Tg</sup> mice reveal delayed recovery from DSS-induced colitis.**

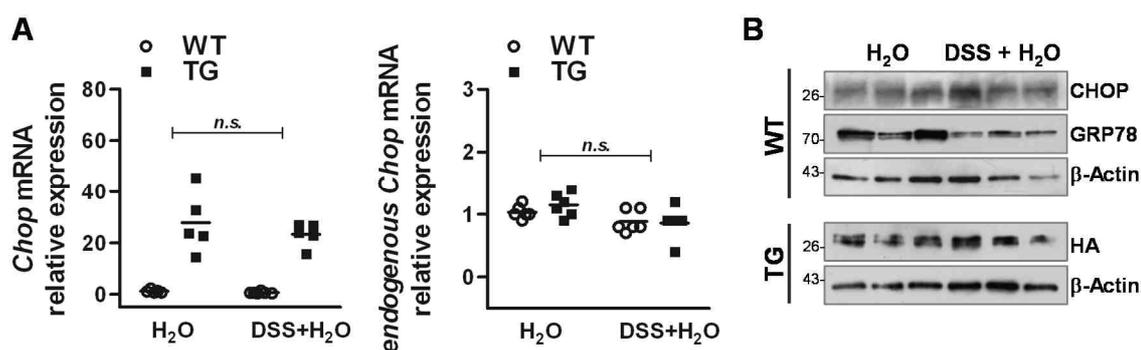

Transgenic mice and wild-type controls ( $n = 6$ ) were orally administered 2% DSS for 5 days followed by a period of 5 days for recovery (DSS+H<sub>2</sub>O). Body weight changes and DAI were monitored daily and data are presented as means  $\pm$ SD. Statistical significance was assessed by Student's t-test,  $P < .05$  (\*) was considered statistically significant.

In the recovery phase, both mRNA and protein expression of endogenous and transgenic CHOP remained unchanged comparing water-treated controls to DSS-treated mice, while GRP78 protein expression was strongly reduced in DSS-treated wild-type controls (Figure 39).

**Figure 38. Delayed recovery of transgenic mice associated with enhanced tissue pathology.**

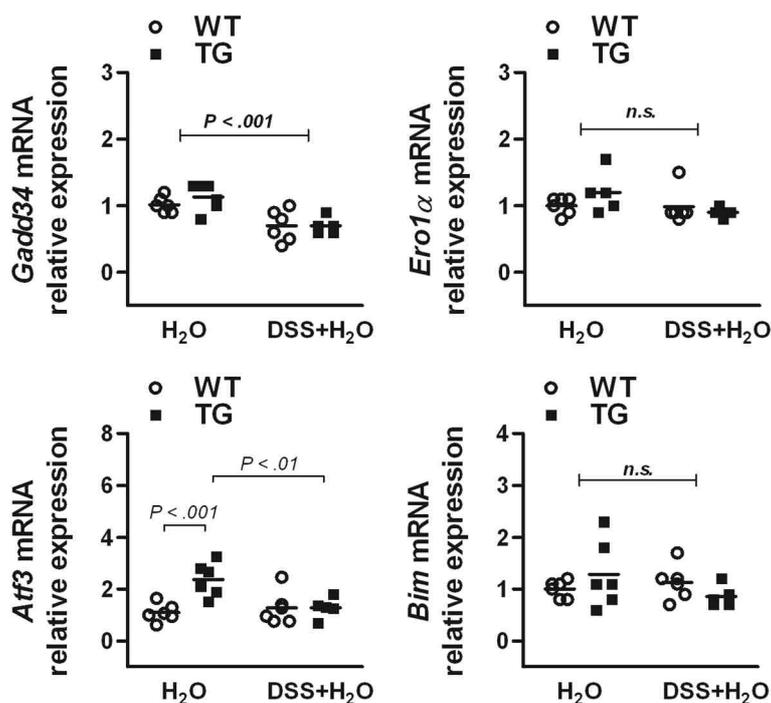

(A) Colonic weight/length ratio was calculated in mg/ml, spleen/body weight ratio in mg/g. (B) Histological scores (0-12) were blindly evaluated regarding colonic tissue damage and immune cell infiltration. Representative H&E stained colonic tissue sections are shown, scale bar represents 200  $\mu$ m. Statistical significance was assessed by Student's t-test,  $P < .05$  was considered statistically significant.

**Figure 39. Expression of endogenous and transgenic CHOP is not regulated upon recovery from DSS-induced colitis.**

Large IECs were isolated from water-treated and H<sub>2</sub>O+DSS-treated mice ( $n = 5-6$ ). (A) The mRNA expression of *Chop* was analyzed by using intron-spanning primer pair and primers specifically binding to the 5'-untranslated region of endogenous *Chop*. Data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  was considered statistically significant. (B) Western blotting ( $n = 3$ ) was performed using antibodies against CHOP, HA-tag, and  $\beta$ -Actin as loading control.

Regarding the mRNA expression of CHOP target genes, IEC-expressed *Gadd34* appeared significantly decreased in response to DSS treatment. *Ero1 $\alpha$* , *Atf3*, and *BIM*, respectively, remained at basal expression levels, even though *Atf3* has been shown to be significantly induced in water-treated *Chop*<sup>IEC Tg/Tg</sup> mice when compared to wild-type controls (Figure 40).

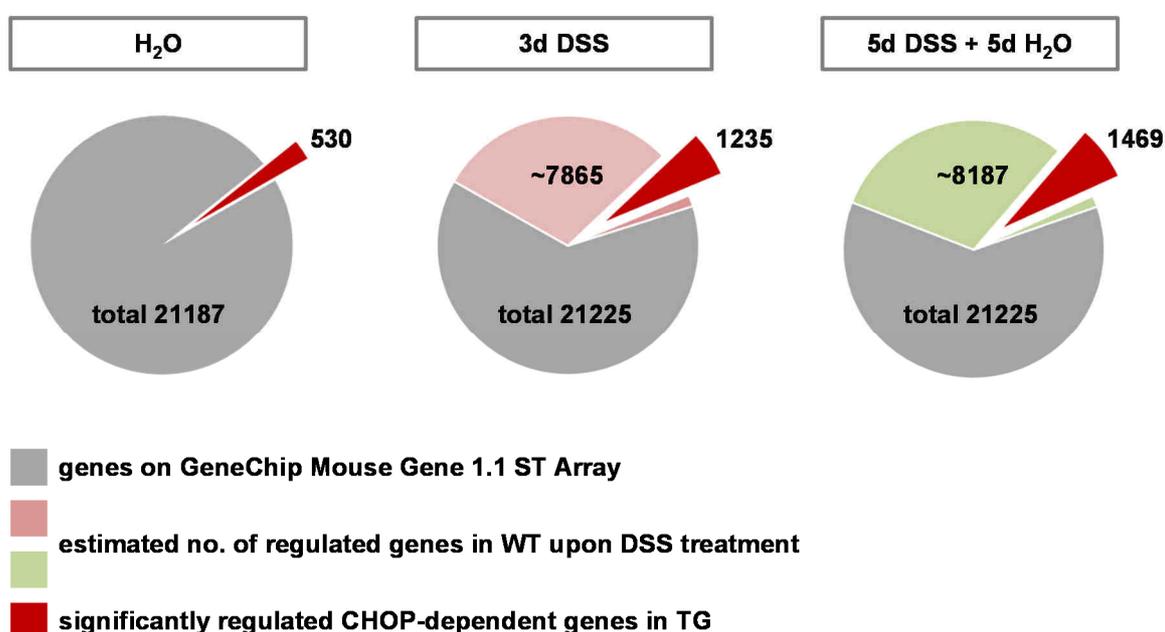

**Figure 40. CHOP target gene expression in the recovery phase of DSS-induced colitis.**

The expression of CHOP target genes *Gadd34*, *Ero1 $\alpha$* , *Atf3*, and *BIM* was analyzed by qPCR using total RNA from isolated large IECs of DSS+H<sub>2</sub>O-treated mice and water-treated controls (n = 5-6). All data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by Holm-Sidak test,  $P < .05$  was considered statistically significant. Significant differences are illustrated considering both genotype and treatment as well as genotype-dependent differences in treatment groups and treatment-dependent differences within one genotype.

Taken together these data suggested that enhanced CHOP protein levels impair mucosal tissue recovery in response to DSS-induced colitis. Even though disease pathology of *Chop*<sup>IEC Tg/Tg</sup> mice might result from the more severe inflammation observed in acute experimental colitis, CHOP-mediated pro-apoptotic signaling could not be confirmed at the level of CHOP target gene expression. Thus, sustained disease severity is highly assumed to be associated with deregulated epithelial regeneration.

### 4.3.3 Disease severity in DSS-treated mice is independent of CHOP-driven apoptosis

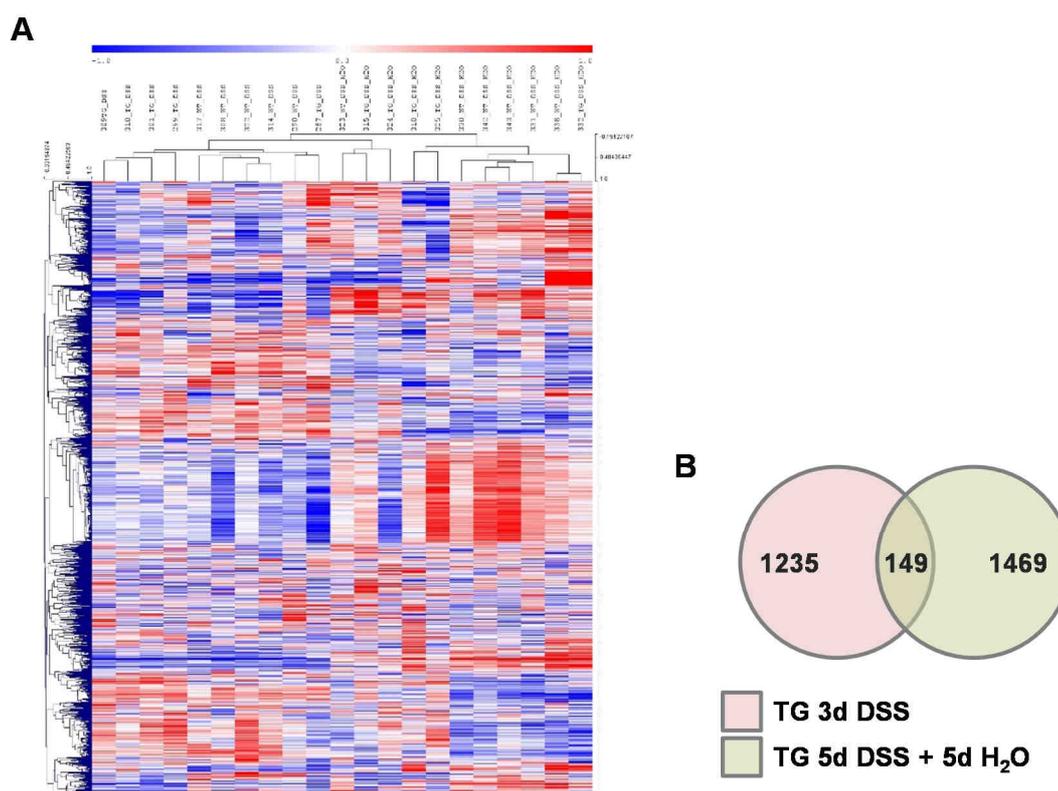

Gene expression profiles of 3 days DSS-treated mice and mice in recovery were analyzed for regulation patterns leading to the more severe colitis phenotype in transgenic mice. Comparison of gene sets from water-treated and DSS-treated transgenic mice as well as wild-type controls, respectively, let assume that approximately 7865 genes might be regulated upon DSS treatment. However, in early inflammation 1235 genes were significantly regulated in *Chop*<sup>IEC Tg/Tg</sup> mice when 3d DSS-treated transgenic mice were compared to 3d DSS-treated wild-type controls, while 1469 genes have been shown to be differently expressed in the recovery phase (Figure 41).

**Figure 41. Overview of CHOP-dependent gene expression upon DSS treatment.**

Gene expression profiles were evaluated comparing WT and TG mice in healthy and unhealthy conditions upon DSS treatment. Numbers of significantly regulated genes in TG mice are presented as CHOP-dependent genes (red). Total gene numbers (grey) referred to the number of genes on Affymetrix GeneChip®. DSS-dependent gene regulation in WT has been estimated because of different batches of microarray experiments (rose/green).

Hierarchical cluster analysis based on log<sub>2</sub>-fold change revealed that gene expression profiles of mice in early inflammation might be rather attributed to DSS treatment than to the genotype of mice (Figure 42A). With regard to CHOP-dependent gene enrichment in DSS-treated mice, 149 genes have been shown to be significantly regulated in both early inflammation and in recovery (Figure 42B).

**Figure 42. Hierarchical cluster analysis of DSS-treated mice.**

Gene expression profiles of 3 days DSS-treated transgenic mice and *Chop*<sup>IEC Tg/Tg</sup> mice in recovery (5d DSS + 5d H<sub>2</sub>O) were assessed by calculating fold changes to adequate DSS-treated wild-type controls. (A) Cluster analysis was performed based on log<sub>2</sub>-fold changes of 3d DSS-treated wild-type and transgenic mice, respectively, and mice in the recovery phase (5d DSS + 5d H<sub>2</sub>O). (B) Significantly regulated genes of 3d DSS- and 5d DSS + 5d H<sub>2</sub>O-treated transgenic mice were further analyzed for overlapping genes.

Top 10 of significantly regulated genes in 3d DSS-treated *Chop*<sup>IEC Tg/Tg</sup> mice are shown in Table 12. In this regard, genes, including *Atf5*, *Trf*, *S100g*, and *Ugt8a*, appeared comparably regulated to water-treated controls (Table 7) as well as *Chop*<sup>IEC Tg/Tg</sup> mice in recovery (Table 13). In contrast, none of the pathways significantly regulated in response to DSS treatment (Table 14) could be observed in water-treated transgenic mice.

In early inflammation, GO term analysis regarding biological process terms (Table 15) revealed reduced numbers of annotated short distance child terms when compared to analysis performed for disease-free transgenic mice (Table 9) and mice in recovery, respectively (Table 16).

In this regard, evaluation of biological process terms has been further performed by using WEB-based GENE SeT AnaLYsis Toolkit <sup>202</sup>. Child terms within the first level in the GO biological process hierarchy have been analyzed regarding gene sets resulting from the overlap analysis (Figure 43).

**Table 12. Most highly regulated genes in 3 days DSS-treated *Chop*<sup>IEC Tg/Tg</sup> mice are shown as TOP 10 up- and down-regulated genes, respectively. Gene enrichment has been evaluated by comparing transgenic mice and wild-type controls upon DSS treatment.**

As shown in Figure 43A, GO analysis considering overlapping gene sets revealed similar distribution patterns of biological process child terms when compared to annotations of individually regulated genes in 3d DSS-treated mice and mice in recovery, respectively. Of note, cell death-associated genes appeared not regulated in a CHOP-dependent manner. 82 genes have been annotated to biological process child term death in early inflammation, while 108 genes seem to be regulatory involved in mechanisms underlying cell death in the recovery phase. In this regard, only 12 genes have been shared, even though both DSS treatments resulted in more severe colitis in transgenic mice when compared to wild-type controls. With regard to total numbers of shared genes, comparison of fold-change values demonstrated that various gene sets were inversely regulated upon DSS treatments (Figure 43B). 70 overlapping genes have been found in total overlap analysis including expression profiles of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice (4.2.1). Herein, comparison of fold-change values revealed similar expression patterns in all three conditions (Figure 43C, Supplementary table 2). Top 10 up- and down-regulated genes of total overlap analysis are presented in Table 17.

**Figure 43. GO analysis of biological process terms regarding gene sets individually and commonly regulated upon DSS treatments.**

Significantly regulated genes in transgenic mice were assessed with regard to gene expression in adequate wild-type controls. (A) Expression profiles of DSS-treated transgenic mice were studied by GO analysis regarding first levels in hierarchy of biological process child terms. Annotations are shown for shared and individually regulated gene sets. (B) Fold-change values of shared genes upon DSS treatment were illustrated in a range of -2 to 2. (C) Total overlap analysis was performed considering significantly regulated genes in disease-free, 3d DSS-treated, and 5d DSS + 5d H<sub>2</sub>O-treated *Chop*<sup>IEC Tg/Tg</sup> mice. Fold-change values of totally shared genes that were regulated in a CHOP-dependent manner were illustrated in a range of -2 to 2.

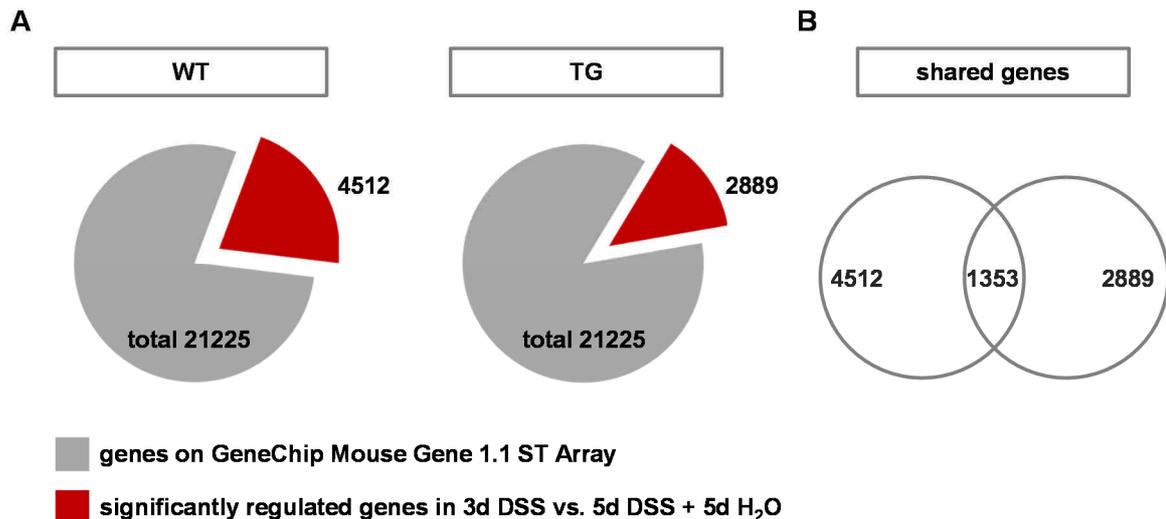

**Table 17. TOP 10 up- and down-regulated genes resulting from overlap analysis of gene sets significantly regulated in disease-free, 3d DSS-, and 5d DSS + 5d H<sub>2</sub>O-treated transgenic mice when compared to adequate wild-type controls.**

Regarding to gene sets in total overlap, changes in gene expression could be observed modulating epithelial cell proliferation as well as cell migration, such as *Tff2* and *Atf5*<sup>218, 219</sup>

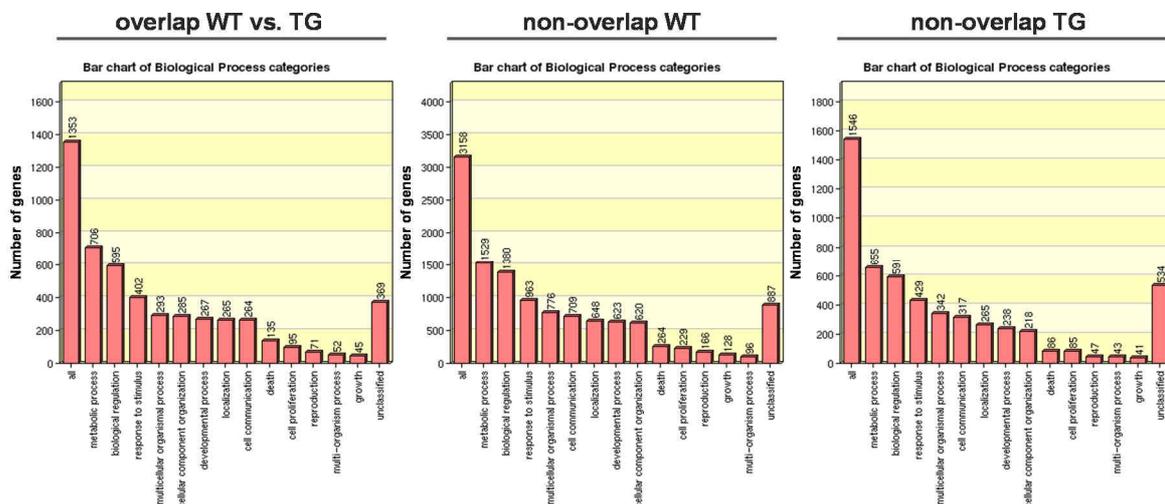

In order to gain a better understanding of gene regulation in the recovery phase, gene expression profiles of transgenic mice and wild-type controls, respectively, were compared between 3 days DSS treatment and recovery. 4512 and 2889 genes were significantly regulated in wild-type and transgenic mice, respectively, when gene expression profiles of 3 days DSS-treated mice were compared to gene regulations in recovery (Figure 44A). In this regard, overlap analysis revealed 1353 shared genes (Figure 44B).

GO analysis for biological process terms showed that 324 and 173 genes were annotated to child terms cell proliferation and growth in wild-type mice, respectively, while 180 and 86 significantly regulated genes were annotated to corresponding child terms in *Chop*<sup>IEC</sup> *Tg/Tg* mice (Figure 45). Herein, 95 (cell proliferation) and 45 genes (growth), respectively, have been shared by *Chop*<sup>IEC</sup> *Tg/Tg* mice and wild-type controls indicating that transgenic mice progressed towards, but were delayed in the recovery phase. However, top 10 up- and down-regulated genes considering overlapping and non-overlapping gene sets are shown in Tables 18-21.

**Figure 44. Gene expression profiles of WT and TG comparing 3d DSS and 5d DSS + 5d H<sub>2</sub>O treatment.**

(A) Significantly regulated genes were assessed in wild-type controls and transgenic mice comparing gene expression profiles of 3d DSS treatment versus 5d DSS + 5d H<sub>2</sub>O. (B) Overlap analysis of genes that are significantly regulated comparing 3d DSS versus 5d DSS + 5d H<sub>2</sub>O showed 1353 shared genes between WT and TG.

**Figure 45. GO analysis of biological process terms regarding gene sets individually and commonly regulated in *Chop*<sup>IEC</sup> Tg/Tg mice and wild-type controls, respectively.**

Gene expression profiles were assessed for WT and TG, respectively, comparing 3d DSS and 5d DSS + H<sub>2</sub>O. Gene sets of WT and TG mice were further analyzed for overlapping and non-overlapping genes (Figure 44). The resulting expression profiles of transgenic mice and wild-type controls were studied by GO analysis regarding first levels in hierarchy of biological process child terms. Annotations are shown for shared and individually regulated gene sets.

In conclusion, these data indicated that DSS-induced colitis in transgenic mice is independent of CHOP-mediated apoptosis. In this regard, susceptibility to DSS-driven colonic inflammation might be rather affected by mechanisms underlying defective epithelial proliferation, consequently leading to decreased regenerative capacity in early inflammation and recovery, respectively.

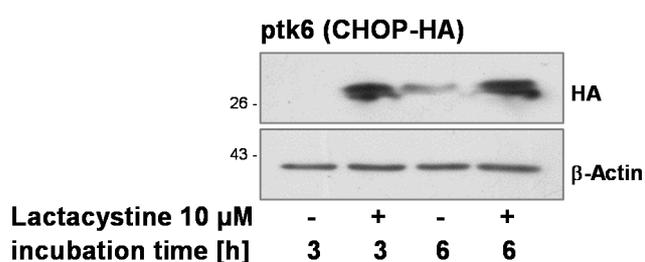

Based on animal experimentation, we further addressed the effects of CHOP on cell proliferation by performing *in vitro* studies in the colonic epithelial cell line ptk6.

#### 4.4 High CHOP protein expression delays cell cycle progression in colonic epithelial ptk6 cells

Enhanced CHOP protein expression has been reported to impact on cell cycle progression *in vitro* by inducing G1 arrest in NIH-3T3 cells <sup>160</sup>. However, recent studies demonstrated that the inhibitory effect of CHOP protein on cell proliferation seemed to be dependent on its subcellular localization, which in turn is strongly dependent on its transcriptional activation. Thus, we addressed two main questions by *in vitro* experimentation <sup>156, 168</sup>. First, we investigated the regulatory mechanisms that might occur in IECs affecting the transcriptional activity of CHOP, and second, we studied CHOP-driven effects on the proliferative capacity of IECs.

##### 4.4.1 Transgenic CHOP-HA protein is degraded by the proteasome and post-translationally modified by phosphorylation

According to previous reports, proteasomal degradation of CHOP-HA protein has been investigated to evaluate the correlation between transgene mRNA expression and CHOP-HA protein levels <sup>152, 153</sup>. Therefore, colonic epithelial ptk6 cells were transfected with pcDNA3.1(-)-CHOP-HA for 24 hours and subsequently treated with the proteasome inhibitor Lactacystine. As indicated in Figure 46, CHOP-HA protein expression is increased in response to Lactacystine treatment.

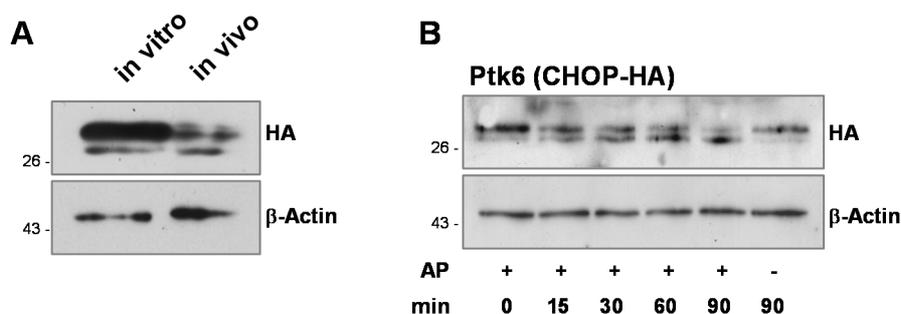

**Figure 46. CHOP-HA undergoes proteasomal degradation in transiently transfected ptk6 cells.**

Colonic epithelial ptk6 cells were transfected with pcDNA3.1(-)-CHOP-HA for 24h followed by incubation with proteasome inhibitor Lactacystine (10  $\mu$ M) for 3h and 6h, respectively. Whole protein extracts were analyzed by Western blotting using anti-HA antibody and anti- $\beta$ -Actin antibody as loading control.

With regard to protein band pattern detected by Western blotting using IEC isolates from transgenic mice, the molecular weight of CHOP-HA differs from ~26 kDa to ~30 kDa. Notably, CHOP-HA protein exhibited similar expression pattern *in vitro* and *in vivo* (Figure 47A).

Since transcriptional activity of CHOP protein is regulated by phosphorylation, CHOP protein band pattern was further analyzed upon dephosphorylation<sup>150, 151</sup>. Treatment of native protein lysates from transfected ptk6 cells with AP yielded into a shift towards lower molecular masses clearly suggesting post-translational modification of CHOP-HA by phosphorylation (Figure 47B).

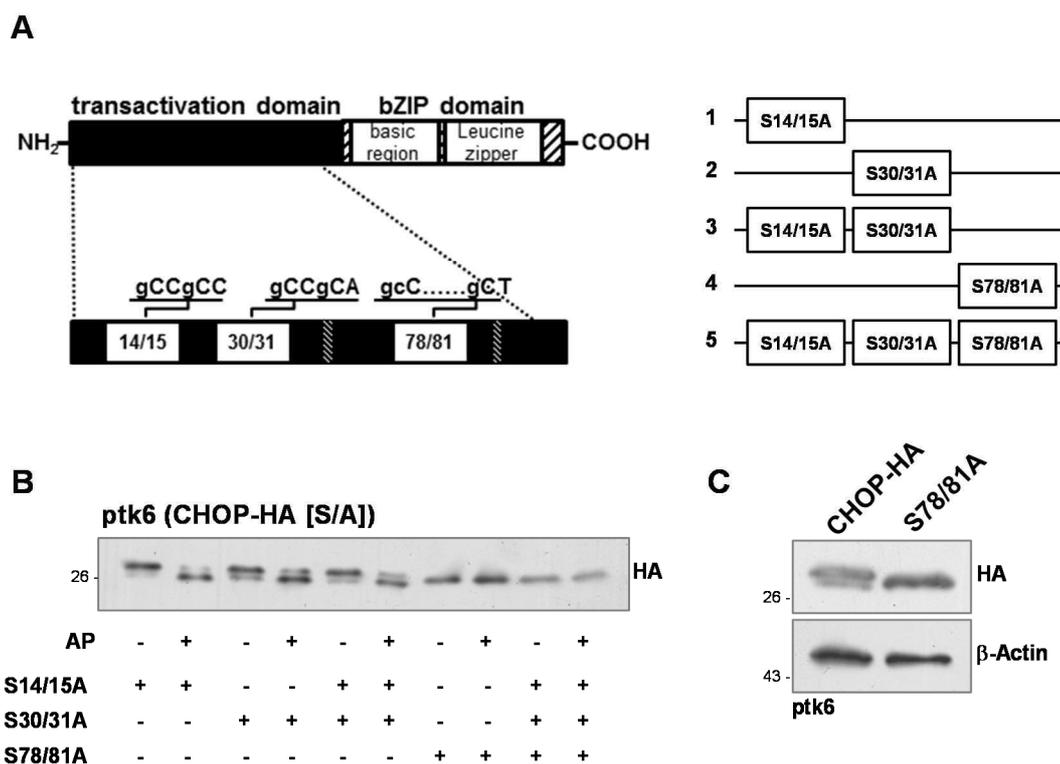

**Figure 47. *In vitro* data indicate post-translational modification of CHOP-HA protein by phosphorylation.**

(A) Protein lysates of CHOP-HA-transfected ptk6 cells and colonic IECs from *Chop*<sup>IEC Tg/Tg</sup> mice were analyzed by Western blotting using anti-HA antibody and anti- $\beta$ -Actin antibody as loading control. (B) Native protein lysates of CHOP-HA transfected ptk6 cells were treated with AP for 0, 15, 30, and 60 min, as well as for 90 min with and without AP. SDS-15% Page was performed followed by Western blot analysis using anti-HA antibody. Shown Western blot data represent 3 independent experiments.

In fact, CHOP protein was found to be phosphorylated by p38 MAP kinase at serine residues 78/81 as well as by casein kinase II at adjacent serine residues 14/15 and 30/31 regulating its transcriptional activation<sup>150, 151</sup>. Consequently, specific serine residues have been replaced by alanine generating plasmid constructs containing CHOP-HA [S14/15A], CHOP-HA [S30/31A], CHOP-HA [S14/15A, S30/31A], CHOP-HA [S78/81A], and CHOP-HA [S14/15A, S30/31A, S78/81A] (Figure 48A).

Transfection of ptk6 cells with mutated plasmid constructs and subsequent treatment of corresponding native protein lysates with AP showed that CHOP-HA protein is post-translationally modified by phosphorylation at p38 MAP kinase-specific phosphorylation sites, serine residues 78/81 (Figure 48B). Accordingly, CHOP-HA [S78/81A] could be detected as a single protein band that indicated a molecular weight comparably to AP-treated protein lysates. Representative Western blot analysis using protein lysates of transfected ptk6 cells with CHOP-HA and CHOP-HA [S78/81A] further confirmed changes in molecular weight due the inhibition of phosphorylation at p38 MAP kinase-specific phosphorylation sites (Figure 48C).

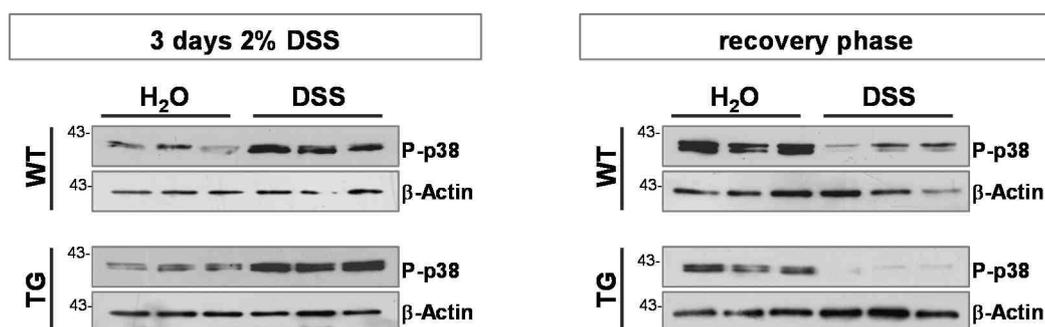

**Figure 48. CHOP-HA is post-translationally modified at p38 MAP kinase-specific phosphorylation sites**

(A) Overview of phosphorylation sites regulating the transcriptional activation of CHOP protein according to Wang et al. (1996) and Ubeda et al. (2003). CHOP mutant constructs were generated replacing specific serine residues by alanine. (B) Non-differentiated ptk6 cells were transfected with mutated CHOP-HA constructs [14/15A], [30/31A], [S14/15A, S30/31A], [S78/81A], and [S14/15A, S30/31A, S78/81A] for 40h. Native protein lysates were incubated with and without AP for 90 min. SDS-15% Page was performed followed by Western blotting using anti-HA antibody. (C) Western blot analysis of protein lysates derived from ptk6 cells expressing CHOP-HA and CHOP-HA [S78/81A] was performed by using anti-HA antibody and anti- $\beta$ -Actin antibody as loading control.

Taken together, these findings suggested that CHOP-HA undergoes post-translational modifications at p38 MAP kinase-specific phosphorylation sites, which is highly associated with the transcriptional activation of CHOP. In contrast, CHOP-HA mRNA-protein correlation is strongly affected by proteasomal degradation, thus reducing the total amount of transgenic protein.

#### 4.4.2 CHOP protein promotes cell cycle delay in colonic epithelial ptk6 cells associated with impaired scratch closure

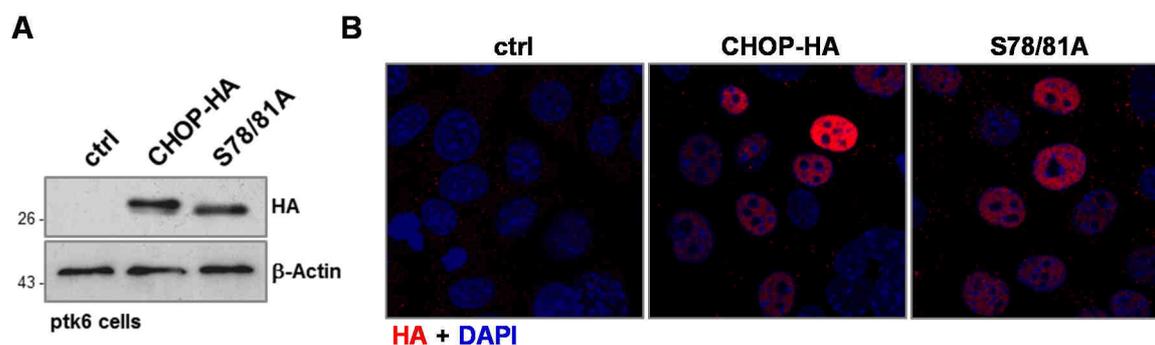

Transcriptional activation of CHOP is strongly associated with cell death<sup>86</sup>. Since CHOP-activating p38 MAP kinase appeared regulatory involved in the post-translational modification of CHOP-HA *in vitro*, p38 MAPK activation was further analyzed upon 3 days DSS treatment and recovery from DSS-induced colitis. As indicated in Figure 22, phosphorylation of p38 MAPK in IECs of *Chop*<sup>IEC Tg/Tg</sup> mice was comparable to wild-type controls. The analysis of IECs derived from DSS-treated mice indicated changes in the phosphorylation status of p38 MAPK similarly regulated in both transgenic and wild-type mice. 3 days DSS-treated mice displayed enhanced activation of p38 MAPK in IECs, while decreased levels of P-p38 MAPK were detected upon recovery from DSS-induced colitis (Figure 49). Notably, Western blot analysis was performed in time with those of Figure 34 and Figure 39 using similar sample volumes. Since P-p38 and  $\beta$ -Actin reveal similar molecular masses (~40 kDa), loading control is indicated by  $\beta$ -Actin of corresponding Western blots. Histon 3 (~19 kDa) was not available as adequate protein loading control.

**Figure 49. Phosphorylation status of p38 MAPK upon 3 days 2% DSS and recovery from DSS-induced colitis.**

Protein lysates of IECs derived from water-treated mice as well as 3 days DSS-treated mice and mice in recovery from DSS-induced colitis ( $n = 3$ ) were analyzed by Western blotting using anti-P-p38 antibody. Protein load is indicated by applying  $\beta$ -Actin on parallel performed Western blots using similar sample volumes.

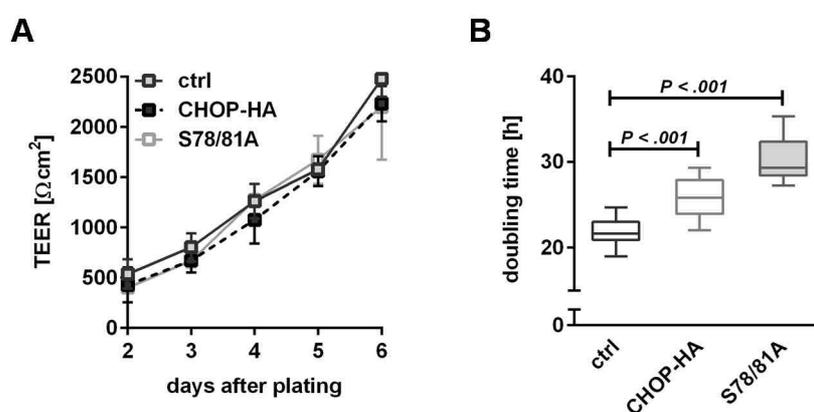

With regard to functional consequences that may be driven in dependence on the phosphorylation status of CHOP protein, we generated stable ptk6 cell lines expressing CHOP-HA and CHOP-HA [S78/81A], respectively (Figure 50A).

**Figure 50. Stably transfected ptk6 cell lines comparably express CHOP-HA and CHOP-HA [S78/81A].**

(A) Western blot analysis was performed using protein lysates derived from stably transfected ptk6 cells. Transgene expression was demonstrated by applying anti-HA antibody and anti- $\beta$ -Actin antibody as loading control. Nuclear localization of CHOP-HA and CHOP-HA [S78/81A] is shown in (B).

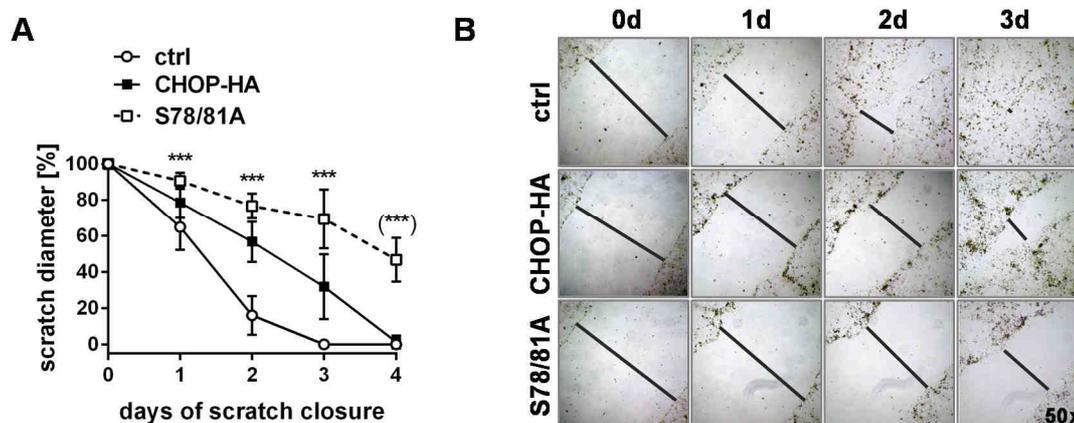

First, we could show that both CHOP-HA and CHOP-HA [S78/81A] protein is mainly located in nuclei of ptk6 cell lines (Figure 50B). Second, we examined the effects of high CHOP-HA and CHOP-HA [S78/81A] expression on barrier function by measuring TEER, showing that neither CHOP-HA nor CHOP-HA [S78/81A] affected the epithelial integrity of ptk6 monolayers (Figure 51A).

**Figure 51. CHOP-HA does not impact on epithelial integrity, but impairs epithelial cell proliferation.**

(A) Epithelial integrity was examined for stable cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A] (technical replicates  $n = 4$ ). TEER measurement was performed for 5 days, starting 2 days after plating cells into transwell inserts. Data in  $\Omega \cdot \text{cm}^2$  are plotted as means  $\pm$  SD. (B) Cell proliferation (technical replicates  $n = 10$ ) was observed for 5 days and evaluated using cell proliferation ELISA. Doubling time was assessed and statistical significance was calculated by non-parametric rank-sum test.  $P < .05$  was considered statistically significant.

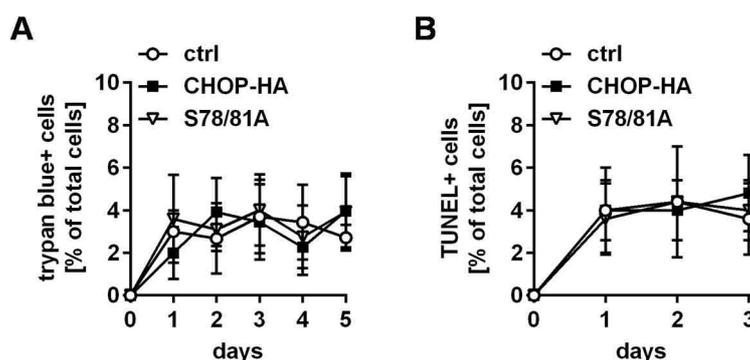

Interestingly, high CHOP protein expression diminished the proliferation of ptk6 cells, which was most decreased in cells expressing CHOP-HA [S78/81A] (Figure 51B). This effect was highly associated with an impaired cell migration evaluated by an *in vitro* scratch wound healing assay (Figure 52).

**Figure 52. CHOP-HA overexpression leads to impaired scratch closure in ptk6 cells.**

(A) Stable ptk6 cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A] were scratched 4 days after reaching confluency (n = 20). Scratch closure was daily monitored and scratch diameter was calculated as percentage of initial scratch size. In non-parametric rank-sum test,  $P < .001$  (\*\*\*) was considered statistically significant. Statistical significance on day 4 refers to differences between ptk6:ctrl and ptk6:CHOP-HA. Scratch closure is shown in (B). Shown data represent 3 independent experiments.

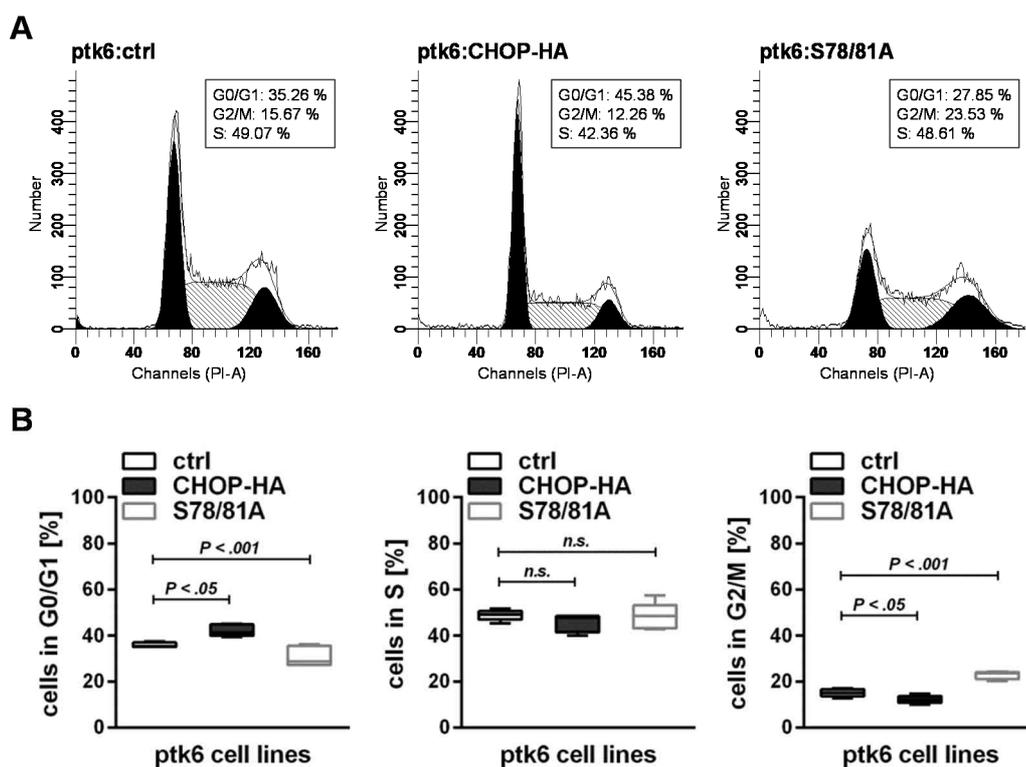

The limit of the proliferative capacity of CHOP overexpressing ptk6 cells seemed to be independent of CHOP-driven cell death induction as both numbers of necrotic and apoptotic cells remained unchanged (Figure 53).

**Figure 53. High CHOP protein expression does not induce cell death in ptk6 cells**

Markers of cell death were monitored in stable cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A]. (A) 20.000 cells/ml were seeded into 24-well plates and numbers of necrotic cells were analyzed by trypan blue staining for 5 days (technical replicates n = 8). (B) 100.000 cells/ml were seeded into 24-well plates and numbers of apoptotic cells were assessed by performing TUNEL assay. Numbers of apoptotic cells were calculated as percentage of total cells (technical replicates n = 4). All data are plotted as means  $\pm$  SD.

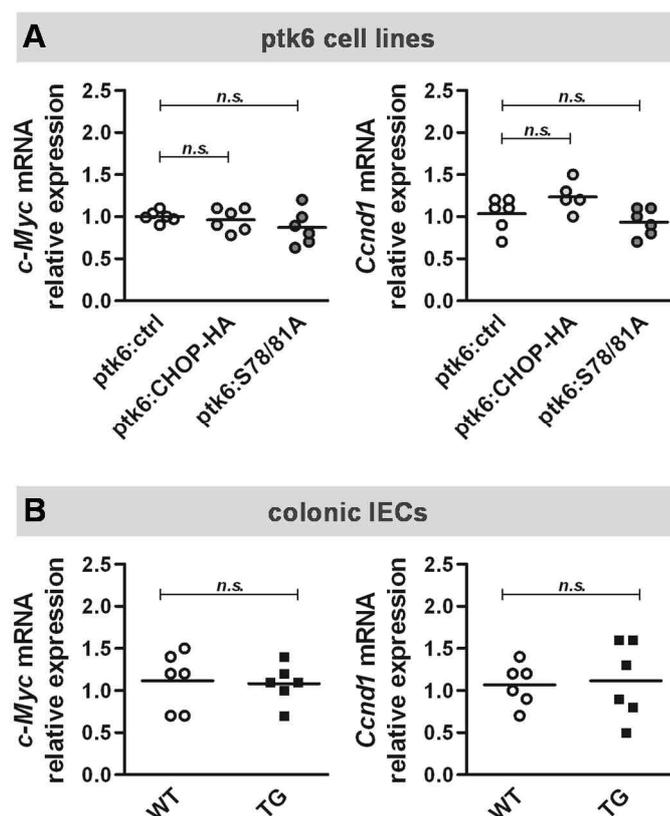

The effect of CHOP-HA and CHOP-HA [S78/81A] overexpression, respectively, on cell proliferation was further evaluated by flow cytometry using propidium iodide DNA staining. As shown in Figure 54, overexpression of CHOP-HA caused cell accumulation in G0/G1 associated with decreased number of cells in G2/M. In contrast, overexpression of CHOP-HA [S78/81A] resulted in increased accumulation of cells in G2/M associated with reduced number of cells in G0/G1. Notably, the S phase of the mitotic cell cycle was not affected by transgene overexpression.

**Figure 54. Enhanced CHOP-HA and CHOP-HA [S78/81A] expression alters cell cycle progression in ptk6 cells.**

(A) Cell cycle of stable ptk6 cell lines ptk6:ctrl, ptk6:CHOP-HA, and ptk6:CHOP-HA [S78/81A], respectively, was analyzed by flow cytometry using propidium iodide DNA staining. (B) Number of cells in G1, S, and G2 phase of the mitotic cell cycle was given as percentage of total cell number. Data are presented as means  $\pm$ SD. Statistical significance was assessed by non-parametric rank-sum test.  $P < .05$  was considered statistically significant. Shown data represent 5 independent experiments.

In the context of proliferation, CHOP has been reported to implicate in Wnt signaling at the level of TCF binding<sup>194</sup>. With regard to these data, c-Myc and Cyclin D1 mRNA expression has been examined in stable ptk6 cell lines and colonic IEC isolates of *Chop*<sup>IEC</sup> <sup>Tg/Tg</sup> mice and wild-type controls. As indicated in Figure 55, both Wnt target genes remained unaffected by CHOP *in vitro* and *in vivo*.

**Figure 55. High CHOP protein expression does not affect Wnt signaling.**

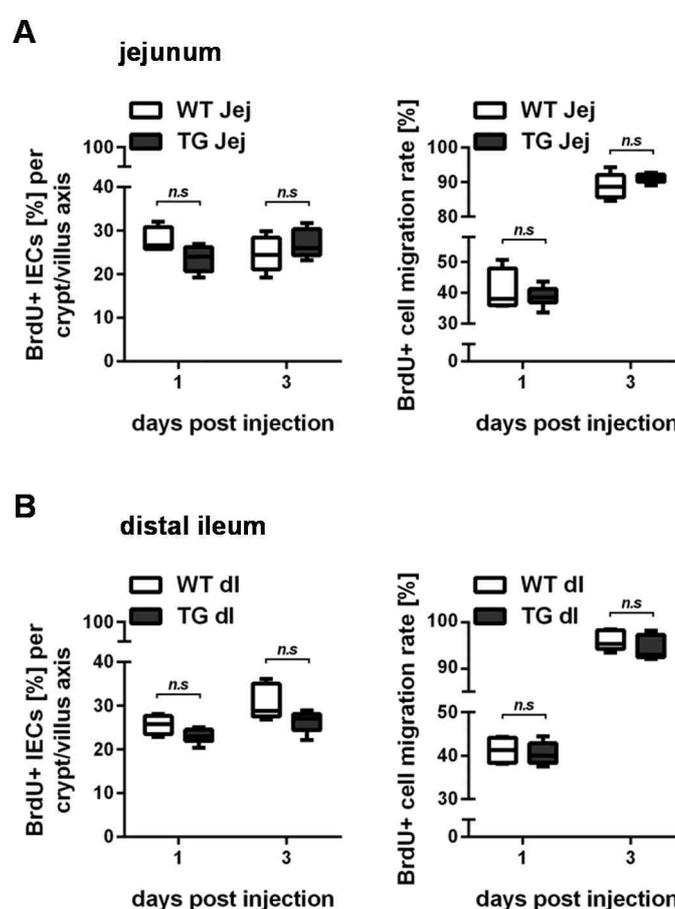

Ptk6 cell lines ptk6:ctrl, ptk6:CHOP-HA, ptk6:CHOP-HA [S78/81A] (A) and colonic IECs of transgenic and wild-type mice (n =6) (B) were analyzed for mRNA expression of Wnt target genes *c-Myc* and *Cyclin D1* by qPCR. Non-confluent cells were harvested at 6 different time points. All data sets were analyzed by non-parametric rank-sum test.  $P < .05$  was considered statistically significant.

In conclusion, these data indicated that CHOP impairs the proliferative capacity of colonic epithelial ptk6 cells independent of CHOP-driven cell death. Both, CHOP-HA and CHOP-HA [S78/81A] affected cell cycle progression associated with decreased cell migration suggesting that enhanced CHOP protein expression implicates in epithelial cell regeneration of *Chop*<sup>IEC Tg/Tg</sup> mice.

Based on these results, proliferation and cell migration of IECs were investigated in *Chop*<sup>IEC Tg/Tg</sup> mice by performing *in vivo* BrdU labeling.

#### 4.5 CHOP overexpression decreases numbers of proliferative cells in transgenic mice associated with impaired mucosal tissue repair

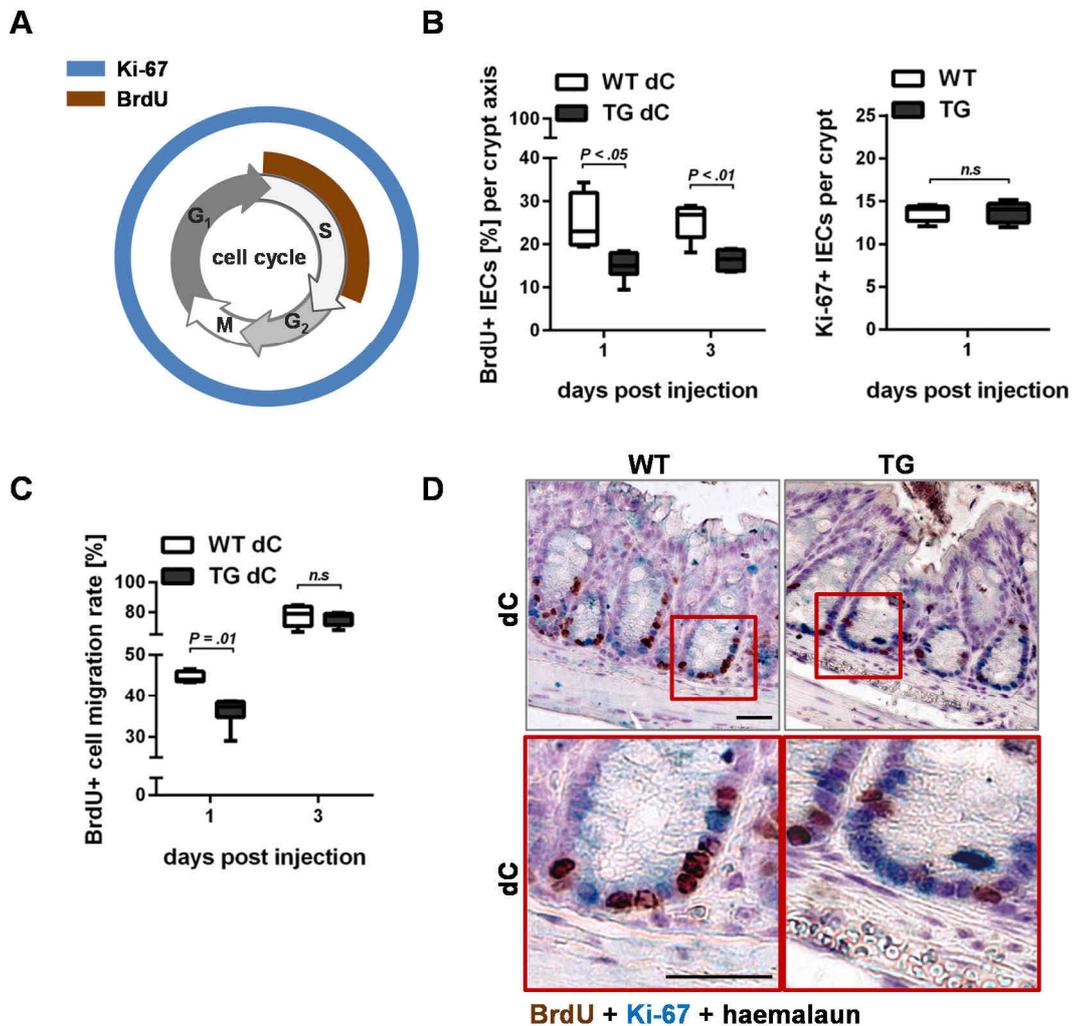

To investigate whether high CHOP-HA expression has an effect on epithelial cell proliferation, disease-free *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls were injected with BrdU for *in vivo* labeling of proliferative cells. Mice were sacrificed on days 1 and 3 post BrdU injection and tissue sections of jejunum, ileum, and distal colon were analyzed for BrdU-positive cells. Numbers of BrdU-positive cells were calculated as percentage of cells along the villus/crypt axis and migration rate of BrdU-positive cells was presented as percentage of distance to villus/crypt tip. As shown in Figure 56, CHOP-HA overexpression did not affect IEC proliferation in jejunum and distal ileum, respectively.

**Figure 56. CHOP-HA overexpression has no effect on epithelial cell proliferation in jejunum and distal ileum of *Chop*<sup>IEC Tg/Tg</sup> mice.**

Transgenic mice and wild-type controls were injected with BrdU for *in vivo* labeling of proliferative cells and sacrificed on days 1 and 3 post injection. 5  $\mu$ m tissue sections of jejunum (A) and distal ileum (B) were analyzed for BrdU-positive cells by IHC. Number of BrdU-positive cells was calculated as percentage of total cell number along the villus/crypt axis. Migration rate of BrdU-positive cells was assessed as percentage relative to villus/crypt height. All data sets were analyzed by non-parametric rank-sum test.  $P < .05$  was considered statistically significant.

In contrast, proliferation of IECs was found to be significantly decreased in distal colon of *Chop*<sup>IEC Tg/Tg</sup> mice when compared to wild-type controls (Figure 57). With regard to the proliferation markers used in this experiment, BrdU-positive cells specifically represented IECs in the S-phase, while Ki-67-positive cells referred to cells in all phases of the cell cycle except G<sub>0</sub> (Figure 57A).

**Figure 57. CHOP-HA overexpression in distal colon leads to reduced numbers of proliferative cells associated with decreased migration.**

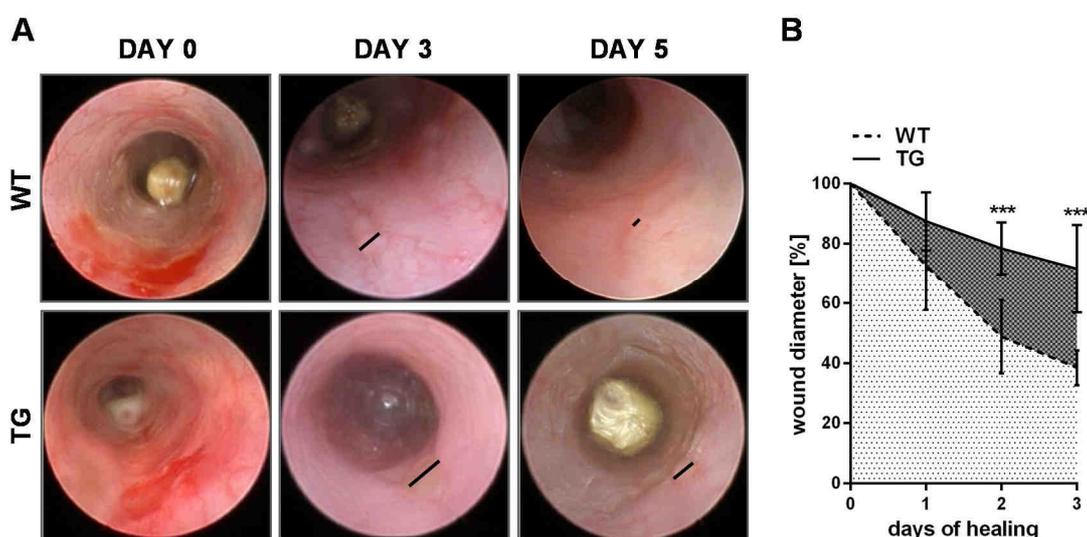

Colonic tissue sections of transgenic mice and wild-type controls sacrificed on days 1 and 3 post BrdU injection ( $n = 5$ ), were analyzed for BrdU- and Ki-67 positive cells. Detection of proliferation markers BrdU and Ki-67 within the cell cycle is illustrated in (A). (B) Numbers of BrdU- and Ki-67-positive cells were assessed by IHC. Numbers of BrdU+ cells are given as percentage to total cell numbers along the crypt axis. Numbers of Ki-67+ cells were assessed per crypt. (C) Migration rate of BrdU-positive cells was assessed as percentage relative to crypt depth. (D) Representative colonic tissue sections from *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls were stained for both BrdU- and Ki-67-positive epithelial cells. Haemalaun was used for nuclear counterstaining. Scale bars represent 50  $\mu\text{m}$ . All data sets were analyzed by non-parametric rank-sum test,  $P < .05$  was considered statistically significant.

Reduced numbers of BrdU-positive IECs were associated with a delayed migration rate of colonic epithelial cells (Figure 57B and C). However, numbers of Ki-67-positive cells remained unchanged in *Chop*<sup>IEC Tg/Tg</sup> mice compared to wild-type controls. Similar results could be assessed in BrdU-labeled mice further illustrated by representative tissue sections of distal colon that were co-stained for BrdU and Ki-67 (Figure 57C and D).

Taken together, these data clearly demonstrated that enhanced CHOP protein expression implicates in cell cycle progression of colonic IECs associated with decreased ratio of BrdU- to Ki-67-positive cells and significantly reduced cell migration.

#### 4.6 CHOP protein impairs wound healing in disease-free transgenic mice

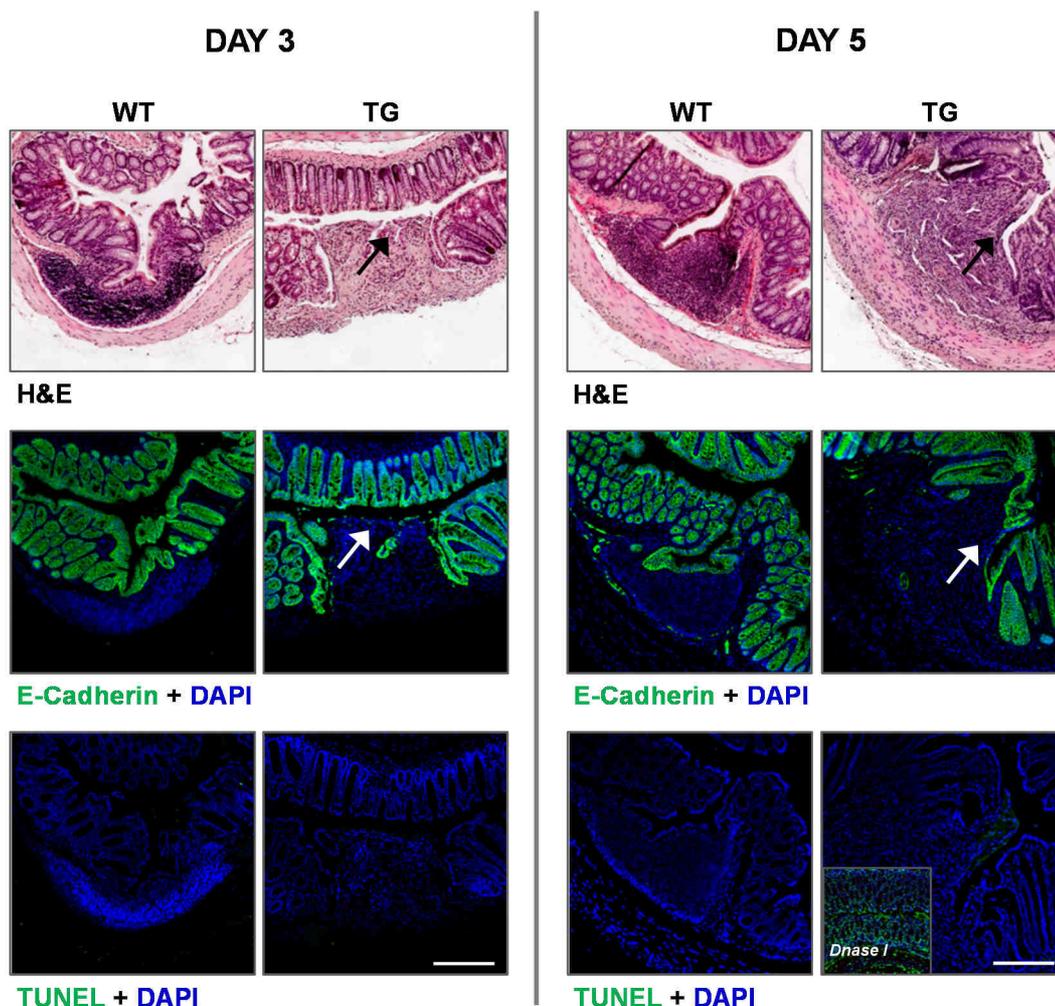

Based on our previous findings, we could show that disease severity in response to DSS treatment is significantly enhanced in *Chop*<sup>IEC Tg/Tg</sup> mice. Since IEC-specific CHOP overexpression further decreased the process of epithelial regeneration upon DSS-induced mucosal tissue damage, we strongly suggested that this effect might be associated with the reduced proliferation and cell migration of colonic IECs observed in disease-free transgenic mice. Following this hypothesis, we next evaluated mucosal tissue repair of mechanically induced wounds. Accordingly, mechanical wounds were induced in colonic mucosa of disease-free *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls. Wound healing was followed by video colonoscopy on days 0, 1, 2, 3 and 5 calculating wound diameters as percentage of initial wound size. In transgenic mice, wound closure was significantly retarded when compared to wild-type controls (Figure 58).

**Figure 58. Wound healing is impaired in *Chop*<sup>IEC Tg/Tg</sup> mice.**

(A) Colonic mucosal lesions were mechanically induced in *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls (n = 6 per group). Wound healing was monitored by video colonoscopy on days 0, 1, 2, 3, and 5. (B) Wound diameters were assessed and calculated as percentage to initial wound size. Data for days 0, 1, 2, and 3 (n = 6) are presented as means  $\pm$ SD. Statistical significance was assessed by Student's t-test,  $P < .001$  (\*\*\*) was considered statistically significant.

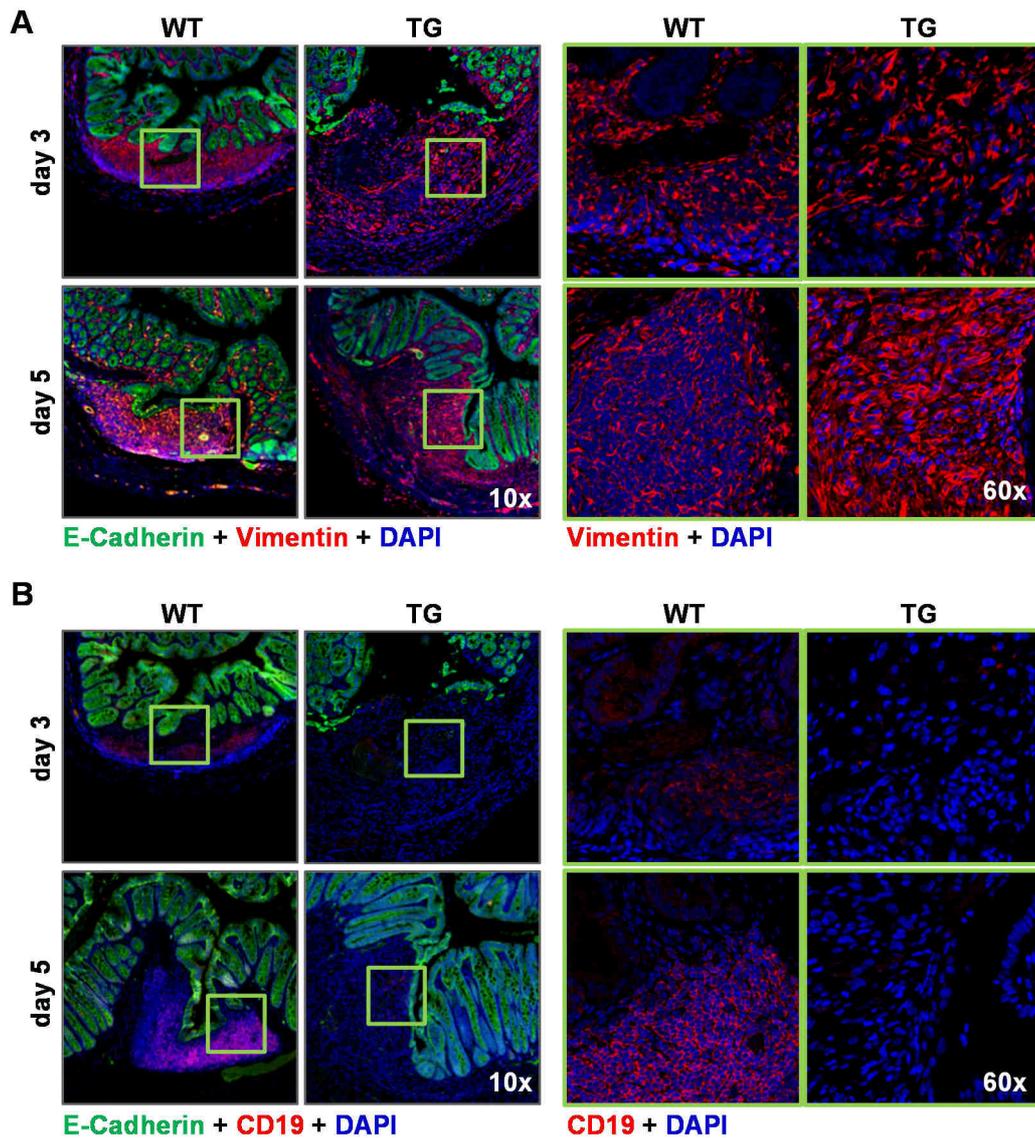

Wound closure was further evaluated at the histological level comparing H&E staining as well as IF for E-Cadherin. Therefore, mice were sacrificed on days 3 and 5 of healing (n = 3 per group and day). As shown in Figure 59, the epithelial cell layer was still disintegrated in *Chop*<sup>IEC Tg/Tg</sup> mice on days 3 and 5 of healing, while healing as sufficiently progressed to wound closure in wild-type controls. Notably, TUNEL assay did not detect apoptotic epithelial cells in wound regions of transgenic mice.

**Figure 59. Transgenic mice show delays in colonic epithelial regeneration.**

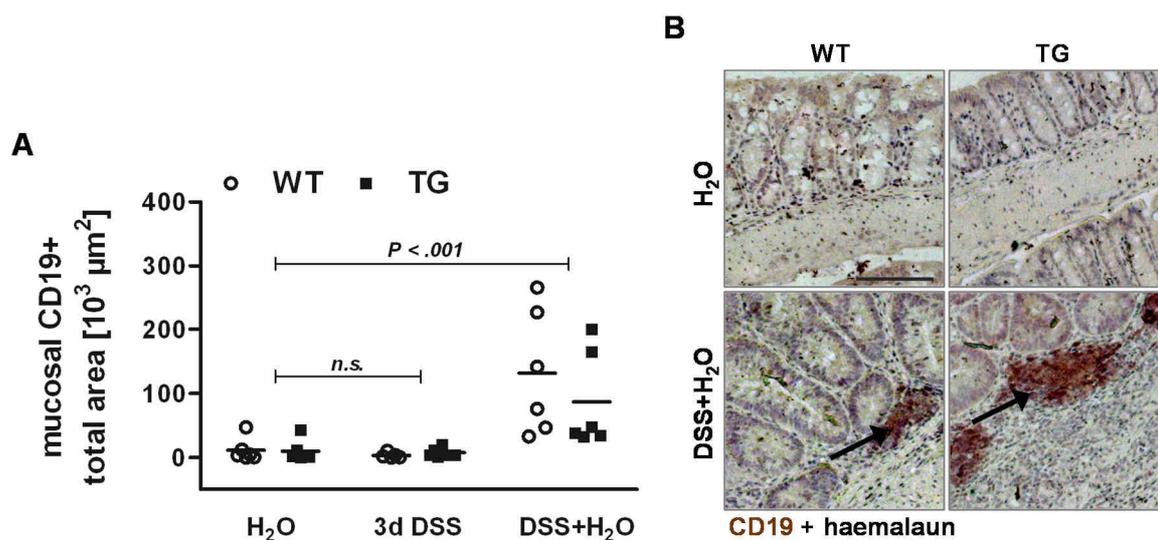

Mice were sacrificed by cervical dislocation at days 3 and 5 ( $n = 3$  per group and day). 5  $\mu\text{m}$ -thick colonic tissue sections of *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls were stained with H&E. IF was performed by using primary antibody against E-Cadherin. DAPI was used for nuclear staining. TUNEL assay was performed after 3 and 5 days of mechanical injury. Positive control was treated with DNaseI. Arrows indicate disrupted epithelial cell layer. Scale bars represent 200  $\mu\text{m}$ .

With regard to wound regions, wild-type mice displayed enhanced immune cell infiltration when compared to *Chop*<sup>IEC Tg/Tg</sup> mice. Analysis of immune cell stainings revealed that progressing wound closure correlated with infiltration of CD19-positive B cells, while delayed wound healing seemed to be associated with increased Vimentin production (Figure 60). In this context, we compared numbers of CD19-positive cells in disease-free and DSS-treated mice, respectively, showing that infiltration with mucosal CD19-positive B cells was specifically enhanced in the recovery phase of DSS-treated mice (Figure 61).

**Figure 60. Delayed wound closure is associated with enhanced Vimentin production and reduced CD19+ immune cell infiltration.**

Mucosal healing was analyzed on days 3 and 5 after wound induction. (A) Tissue sections containing wound regions were stained for Vimentin as a marker for fibroblasts. E-Cadherin staining was performed illustrating the epithelial cell layer. DAPI was used for nuclear counterstain. (B) Tissue sections were analyzed for B cell infiltration using anti-CD19 antibody. E-Cadherin staining was performed to illustrate the epithelial cell layer. DAPI was used for nuclear counterstain.

**Figure 61. Mucosal CD19+ cell infiltration in response to DSS treatment.**

(A) Colonic tissue sections of disease-free and DSS-treated mice were analyzed for CD19-positive cells by IHC. CD19-positive areas were measured in whole Swissroll sections. Data are presented as CD19+ area in total tissue area. Data sets were analyzed by TWA with genotype and DSS treatment as main factors followed by multiple comparison procedure by Holm-Sidak method,  $P < .05$  was considered statistically significant. (B) IHC of representative tissue sections is shown for disease-free mice and mice in recovery. Arrows indicate CD19-positive B cell accumulation, scale bar represents 200  $\mu\text{m}$ .

In summary, these findings suggested that enhanced CHOP protein expression does not only affect the severity of inflammation in DSS-induced colitis, but rather implicates in epithelial regeneration in response to mechanically induced mucosal wounds, thus leading to prolonged tissue damage and impaired mucosal healing.

## 5 Discussion

IBD are multifactorial disorders that are strongly associated with immunological dysfunction. In this regard, maintenance of epithelial integrity highly contributes to the intestinal immune homeostasis. Deregulated epithelial cell signaling has been reported to affect innate immune mechanisms, thus promoting the development of chronic inflammation<sup>38, 220</sup>. Epithelial integrity is strongly dependent on epithelial turnover that is tightly regulated by various mechanisms underlying cell proliferation and apoptosis<sup>169, 186, 221</sup>. In this context, CHOP has been shown to be involved in both apoptosis and proliferation<sup>54, 160</sup>. Even though direct implications of CHOP in IBD remains elusive, inflammation-related signaling leading to CHOP expression has been linked to the disease phenotype. Both, ER UPR and mtUPR were up-regulated in IBD, while CHOP expression has been observed to be significantly reduced at mRNA and protein levels in UC<sup>28, 40, 164, 165</sup>. With regard to previous studies, consequences of CHOP-mediated signaling has been attributed to pro-apoptotic effects rather than mechanisms involved in the regulation of cell proliferation<sup>86</sup>. Subsequently, CHOP down-regulation in colonic inflammation might reflect protective mechanisms; which first let assume that CHOP expression does not correlate with IBD-associated apoptosis and further raise the question of whether CHOP is regulated in an UPR-independent manner.

To address the IEC-specific function and consequences of CHOP protein expression in the context of intestinal inflammation, a genetically modified mouse model (*Chop*<sup>IEC Tg/Tg</sup>) was generated conditionally overexpressing CHOP in the intestinal epithelial layer. We characterized the effects of high CHOP protein expression in disease-free mice and mice that were challenged by colitis-inducing *C. rodentium* and DSS, respectively.

Our findings demonstrate for the first time that IEC-expressed CHOP does not promote apoptotic signaling, but strongly affects the proliferative capacity of epithelial cells. Even though disease-free mice seemed to compensate reduced proliferation of colonic epithelial cells, defective proliferation impairs epithelial regeneration in response to mucosal tissue damage. In this regard, decrease in the regenerative capacity is highly suggested to cause enhanced susceptibility to early DSS-induced inflammation as well as delayed mucosal healing of DSS-induced tissue damage. Along this line, down-regulation of CHOP in UC might contribute to an increased epithelial turnover as a consequence of inflammation-driven apoptosis<sup>164, 169</sup>. In conclusion, our study provides important insights into IEC-specific signaling and consequences underlying environmental challenges that affect gut homeostasis in health and disease.

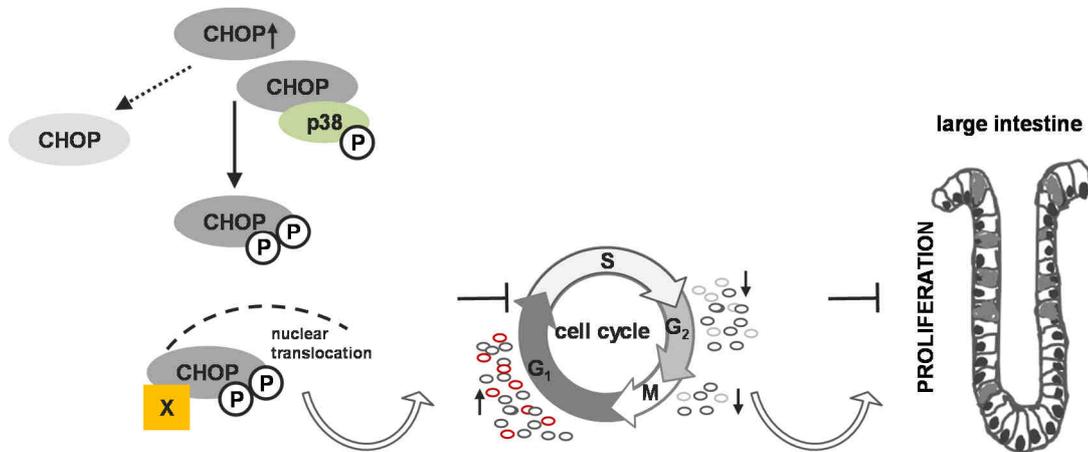

## 5.1 High CHOP protein expression leads to defective proliferation of IECs

First, we characterized *Chop*<sup>IEC Tg/Tg</sup> mice, demonstrating that high CHOP protein expression in IECs does not cause spontaneous inflammation in the intestine. IEC phenotype of transgenic mice was comparable to healthy wild-type controls considering morphological alterations as well as inflammatory pathology, including immune cell infiltration, mucus production, and changes in both apoptotic (Caspase 3 cleavage) and proliferative (Ki-67) rate. With regard to previous studies, CHOP expression is frequently described in correlation with the onset of apoptosis mediated by various ER stress-inducing agents, such as tunicamycin, breveldin A, and thapsigargin<sup>54, 222</sup>. In pro-apoptotic conditions, transcriptional activation of CHOP is mediated by phosphorylation through p38 MAP kinase as well as dimer formation with specific binding partners, such as C/EBP $\beta$ <sup>151, 156</sup>. In this context, Chiribau et al. showed that protein expression of both CHOP and binding partner C/EBP $\beta$  isoform LIP was strongly dependent on ER stress signaling<sup>156</sup>. We could not find elevated ER stress as well as enhanced p38 MAP kinase activation in *Chop*<sup>IEC Tg/Tg</sup> mice when compared to wild-type controls, while LIP expression remained below detectable levels (data not shown). Thus, we strongly suggested that CHOP-induced cell death might be regulated by several interrelated apoptotic mechanisms that are absent in IECs of non-stressed transgenic mice. In fact, also the expression of CHOP is tightly regulated in non-stressed cells. Various transcriptional, post-transcriptional, and post-translational regulation patterns limit the expression of CHOP under physiological conditions<sup>147-149, 153</sup>. Since transgenic CHOP is controlled by the CAGGS promoter, we exclusively analyzed mechanisms affecting CHOP protein expression. According to cell culture experiments performed with the colonic epithelial ptk6 cell line, we could show that transgenic CHOP protein is degraded by the proteasome. Hence, we suggested that transgene mRNA expression and CHOP protein abundance did not correlate in *Chop*<sup>IEC Tg/Tg</sup> mice. Even though protein levels might be decreased in transgenic mice, CHOP is still largely expressed when compared to wild-type controls. Interestingly, we found that transgenic CHOP is strongly accumulated in nuclei of IECs. In this regard, it has been assumed that CHOP does not possess a functional nuclear localization site, which in turn makes nuclear translocation strongly dependent on heterodimer formation<sup>156</sup>. Unfortunately, analysis of heterodimer formation by performing immunofluorescence double staining with antibodies against HA and C/EBP $\beta$  (LAP, LIP), ATF3, and ATF4, respectively, remained without results (data not shown). Nevertheless, nuclear translocation of CHOP protein pointed towards its transcriptional activation. We thus examined CHOP target gene expression, including ER stress-responsive genes, such as *Gadd34*, *Ero1 $\alpha$* , *Atf3*, *BIM*, as well as mtUPR-specific *Cpn60* expression. Herein, only *Atf3* was significantly regulated (+2,7-fold) at mRNA expression level following gene expression profile

of colonic epithelial cells derived from *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls. ATF3 has been reported to form dimers with CHOP, but it remains elusive how these proteins may interact with each other in transgenic mice<sup>155</sup>. However, with regard to the expression patterns of nuclear CHOP protein, we found patchy distributions along the vertical axis, which might result from proteasomal degradation<sup>152-154</sup>. In this context, it is worth mentioning that *vil-Cre* mice were used for the generation of *Chop*<sup>IEC Tg/Tg</sup> mice that have been reported to equally express Cre recombinase along the vertical and horizontal axis of the intestine<sup>206</sup>. Another indication of post-translational modification was given by Western blot analysis detecting CHOP-HA protein bands with different molecular weights (~26 kDa - ~30 kDa). According to previous findings demonstrating that CHOP became phosphorylated in order to promote or inhibit its transcriptional activity, respectively, we investigated banding patterns of several protein variants lacking specific phosphorylation sites<sup>150, 151</sup>. Following this approach, we found that CHOP became partly phosphorylated at p38 MAP kinase-specific phosphorylation sites *in vitro*, suggesting similar post-translational regulation patterns *in vivo*. Phosphorylation at serine-residues 79/82 (human) and 78/81 (mouse) has been strongly associated with enhanced transcriptional activity of CHOP protein in response to prolonged ER stress, which in turn favors apoptosis of unhealthy cells<sup>151</sup>. Contrary, we clearly showed that both transgenic CHOP protein as well as the [S78/81A] protein variant were involved in the regulation of epithelial cell proliferation, but not apoptosis/necrosis, following our cell culture experiments with colonic ptk6 cell lines. As a consequence, we hypothesized that CHOP rather implicates in IEC proliferation than cell death *in vivo*.

Little is known about the effects of CHOP on cell proliferation. In 1994, Barone et al. first described that microinjection of CHOP expression plasmids into NIH-3T3 cells led to cell-cycle G1 arrest<sup>160</sup>. Since then just a few studies supported a correlation between CHOP expression and proliferation. Horndasch et al. clearly demonstrated that CHOP is implicated in Wnt signaling in *Xenopus larvae*, thereby suppressing the expression of Wnt target genes, including *c-Myc*<sup>194</sup>. Thus, we further examined epithelial proliferation in *Chop*<sup>IEC Tg/Tg</sup> mice. Distinct markers have been applied to determine proliferative cells<sup>223</sup>. The antigen Ki-67 can be detected in all phases of the cell cycle except G0, while BrdU incorporation exclusively takes place during DNA replication. Since we found numbers of Ki-67-positive cells unchanged in *Chop*<sup>IEC Tg/Tg</sup> mice and wild-type controls, we analyzed BrdU incorporation in IECs. We could show that numbers of BrdU-positive IECs were significantly reduced in transgenic mice associated with decreased cell migration rate. Notably, these effects could just be observed in colon, but not jejunum and ileum of *Chop*<sup>IEC Tg/Tg</sup> mice, which might be explained by basic differences between small and large intestine considering gene expression profiles as well as responsiveness to changes in the basal expression levels<sup>165</sup>. In accordance to our *in vitro* studies, we strongly suggested that CHOP did not affect total

numbers of proliferative colonic IECs, but numbers of cells entering the S phase for DNA replication, which in turn resulted in an accumulation of cells in G1 (Figure 62).

**Figure 62. Hypothetic inhibitory function of CHOP on cell cycle progression in colonic IECs.**

Overexpression of CHOP protein results in increased post-translational modification of CHOP at p38-specific phosphorylation sites, serine-residues 78 and 81. Since CHOP is suggested to lack a functional nuclear localization signal, nuclear translocation is mediated by heterodimer formation with CHOP binding partner X. Enhanced CHOP protein expression impacts on cell cycle progression by inducing accumulation of cells in G1, which *in vitro* is rather associated with depletion of cells in G2/M. The CHOP-mediated delay in cell cycle progression leads to impaired proliferative capacity of colonic IECs, which consequently affects the cell migration rate along the crypt axis.

Defective proliferation in *Chop*<sup>IEC Tg/Tg</sup> mice as well as adequate ptk6 cell lines was not associated with reduced mRNA expression of Wnt target genes, including *c-Myc* and *Cyclin D1*. Wnt signaling occurs most prominently in intestinal stem cells at the crypt base, but is reduced along the vertical crypt axis from stem cell populations to transit amplifying cells<sup>224</sup>. In this context, Heijmans et al. recently reported that the expression of stem cell-specific genes was inversely correlated with the activation of ER stress-responsive genes. Enhanced ER stress signaling appeared highly associated with IEC differentiation, while CHOP expression has been strongly suggested to be substantially involved in mechanisms underlying the loss of stem cell properties<sup>42</sup>. In *Chop*<sup>IEC Tg/Tg</sup> mice, the transgene was only expressed in small amounts regarding IECs at crypt base of small and large intestine, respectively. Therefore, CHOP might not have any effects on proliferation of stem cell populations. Highly decreased CHOP protein expression in intestinal stem cells could either result from proteasomal degradation or incomplete *Cre*-recombination. It is not clear to which extent *vil-Cre*-mediated recombination affected stem cell populations in *Chop*<sup>IEC Tg/Tg</sup> mice. Hence, we might assume incomplete *Cre*-recombination in Lgr5-positive stem cells, but not in TA cells. In general, this aspect could be further investigated by using *Lgr5-Cre*-positive

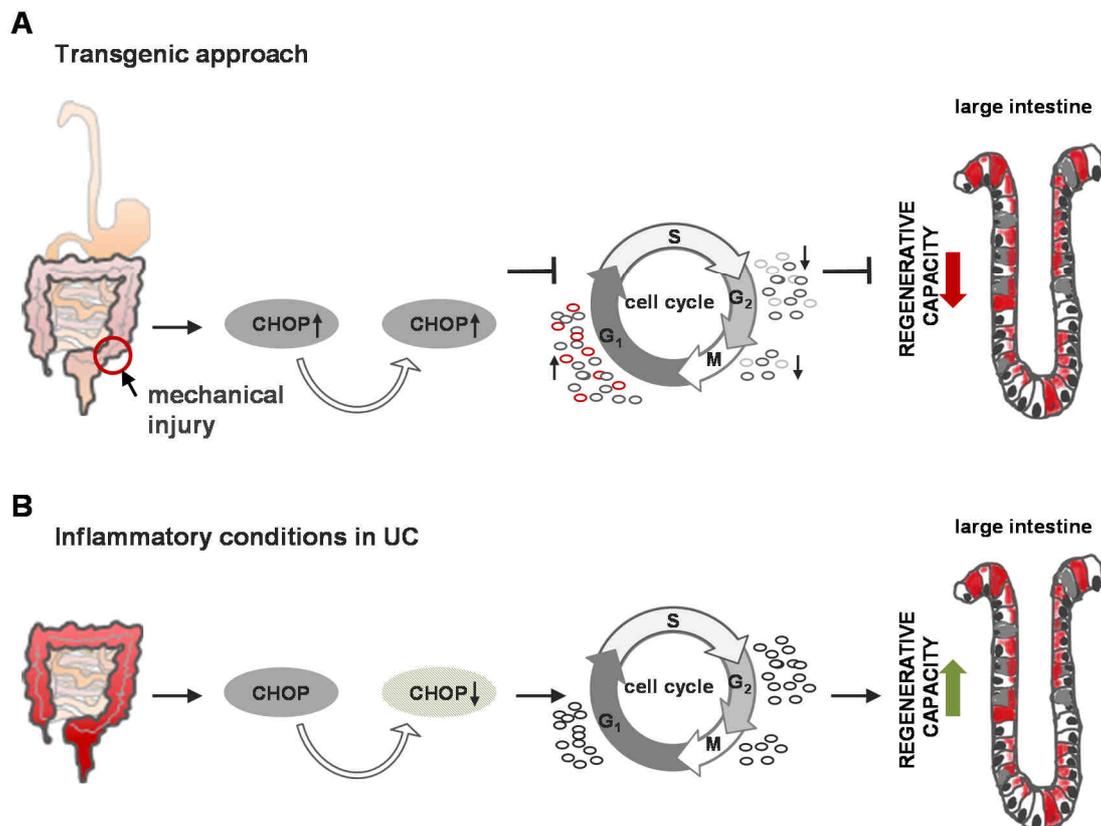

mice. As a consequence of both, transgenic CHOP protein expression is strongly suggested to reduce proliferation of TA cells rather than Lgr5-positive stem cells. In this case, differences in Wnt target gene expression could be below detectable levels when both TA and stem cells were mixed during IEC isolation. However, increasing rates of both epithelial cell proliferation and apoptosis have been observed in UC patients, while CHOP mRNA and protein expression has been reported to be reduced in UC <sup>164, 169, 225</sup>. With regard to our data, these findings strongly suggested that the regulation of CHOP expression most likely underlies mechanisms controlling disease-related epithelial proliferation rather than apoptosis.

## 5.2 Defective proliferation of IECs aggravates mucosal tissue regeneration

Disease-free *Chop*<sup>IEC Tg/Tg</sup> mice exhibited highly significant changes in the expression of gene sets annotated to the biological process GO term response to stimulus, including the child terms defense response, and response to wounding. In this context, we observed alterations in the gene expression program strongly associated with proliferation and cell migration. To investigate whether CHOP-mediated defects in IEC proliferation implicates in epithelial integrity, we determined barrier-forming ability of CHOP overexpressing ptk6 cell lines by measuring TEER. We could show that transgenic CHOP as well as CHOP-HA[S78/81A] did not affect barrier function, thus strongly suggesting that CHOP did not impact on the epithelial barrier in transgenic mice. However, according to further *in vitro* studies, we observed that defective proliferation was strongly associated with impaired cell migration following delayed scratch closure in differentiated ptk6 cell monolayers. Along this line, we examined wound closure of mechanically induced colonic injuries, demonstrating that transgenic mice were significantly retarded in mucosal tissue healing independent of enhanced apoptosis. In fact, intestinal wound healing comprises three cellular events considering re-epithelialization, including epithelial restitution, proliferation, and differentiation<sup>226</sup>. In this context, *Wnt5a* has been shown to play an important role in colonic crypt regeneration<sup>227</sup>. *Wnt5a* describes a non-canonical Wnt ligand that has been reported to inhibit proliferation of canonical Wnt-active IECs. In regenerative conditions, mesenchymal cell-derived *Wnt5a* has been associated with mucosal invaginations upon colonic crypt formation<sup>227</sup>. Disease-free *Chop*<sup>IEC Tg/Tg</sup> mice revealed enhanced expression of *Wnt5a* (+1.5-fold) following gene expression profiles of colonic epithelial cells. Since IEC-derived *Wnt5a* did not promote wound healing in *Chop*<sup>IEC Tg/Tg</sup> mice, we strongly suggested that up-regulation of *Wnt5a* contributed to intrinsic mechanisms underlying the differentiation process of IECs, which in turn caused impaired epithelial proliferation<sup>228</sup>. To further address the correlation between CHOP and *Wnt5a* upon IEC differentiation, corresponding expression levels could be analyzed in sorted cell populations. However, impaired mucosal tissue regeneration was further associated with deficiency of mucosal infiltrating CD19-positive lymphocytes that have been recently reported to contribute to wound healing in skin tissue<sup>229</sup>. Since we found CD19-positive cells in transgenic mice that recovered from DSS treatment, we assumed that infiltration of cells was just delayed, but not absent in mechanically injured *Chop*<sup>IEC Tg/Tg</sup> mice.

Conclusively, we demonstrated that CHOP-induced defects in IEC proliferation consequently diminished the regenerative ability of the epithelial lining, even though epithelial integrity could be maintained in non-challenged conditions. Thus, we strongly suggested

that down-regulation of CHOP in UC promotes epithelial cell proliferation in order to enhance healing of inflammation-driven mucosal tissue damage (Figure 63).

**Figure 63. Possible consequences of CHOP down-regulation under chronic inflammatory conditions.**

(A) High CHOP protein expression impairs cell cycle progression of colonic IECs. CHOP is suggested to lack a functional nuclear localization sequence. Thus, nuclear translocation is mediated by dimer formation with CHOP binding partner X. As a consequence, cells accumulate in G<sub>1</sub>, which *in vitro* is rather associated with depletion of cells in G<sub>2</sub>/M. CHOP-induced delay in cell cycle progression is highly associated with reduced proliferation and cell migration that in total decreases the regenerative ability of the epithelial lining in response to mechanical injury. (B) Proposed consequences of CHOP down-regulation in chronic intestinal inflammation. Down-regulation of CHOP mRNA and protein expression is suggested to contribute to the regenerative capacity of the epithelial lining and in healing of inflammation-driven mucosal tissue damage.

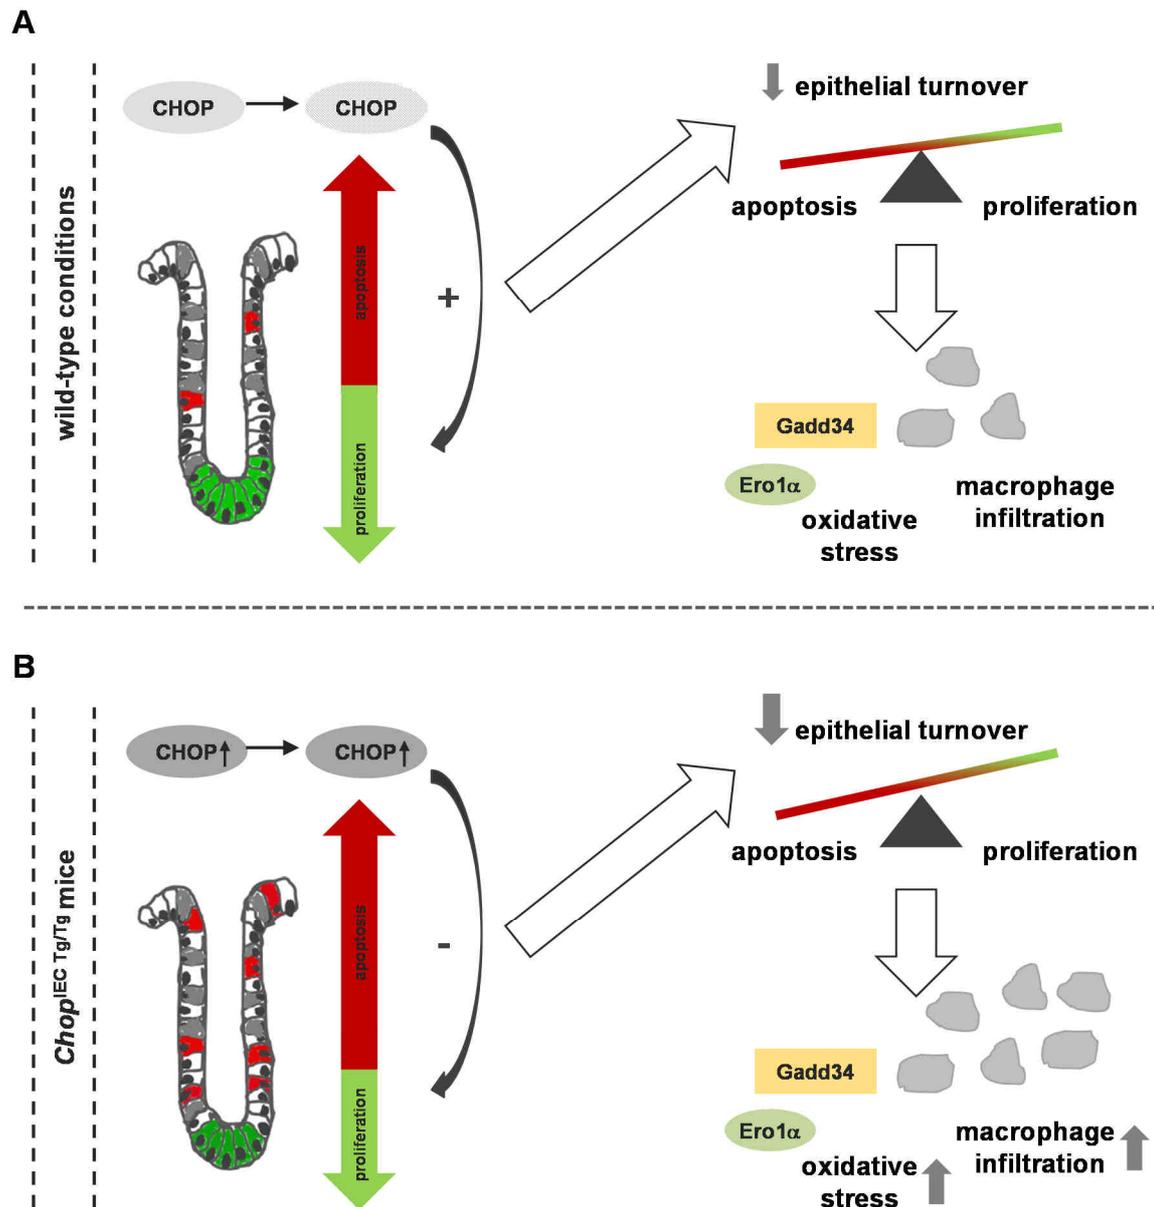

### 5.3 Epithelial barrier function is maintained upon *C. rodentium* infection

Alteration of epithelial turnover has been described in the context of host adaptation to gut microbiota, including commensals and pathogens. In this regard, Savage et al. showed that IEC turnover rates were accelerated in conventional mice when compared to mice that have been raised under germ-free conditions<sup>230</sup>. In turn, defective IEC turnover rates seemed to drive changes in the gene expression profile of *Chop*<sup>IEC Tg/Tg</sup> mice highly associated with the bacterial defense program. Thus, we suggested that defects in IEC proliferation were compensated with enhanced expression of anti-microbial peptides, such as Reg3 family members (+2-fold), lactoperoxidase (+1.5-fold), and lysozyme 1 (+1.3-fold). However, it has been demonstrated that defective proliferation was strongly associated with impaired bacterial clearance in response to *C. rodentium* infection<sup>231</sup>. With regard to our data, we could show that clearance of *C. rodentium* remained unchanged upon sustained CHOP expression, suggesting that defective proliferation did not further affect epithelial barrier function in *Chop*<sup>IEC Tg/Tg</sup> mice. Even more, we demonstrated that up-regulation of anti-microbial peptides had no effect on the onset of *C. rodentium* colonization. Even though Reg3 $\beta$  seemed to be involved in host response to *C. rodentium* infection considering colonic tissue staining of infected transgenic mice and wild-type controls, CHOP-driven up-regulation of Reg3 $\beta$  did not confer an advantage in a preconditioning fashion. Since we exclusively analyzed mice on day 25 dpi, it is difficult to interpret tissue pathology of *C. rodentium*-driven colitis. Even though there seemed to be no differences in morphological changes between transgenic mice and wild-type controls, further studies on the infection course considering more time points might give more information. However, Sellin et al. reported that *C. rodentium* stimulated  $\beta$ -catenin signaling, thereby inducing colonic crypt hyperplasia<sup>232</sup>. Thus, *C. rodentium*-induced signaling might reverse the negative effects of CHOP on epithelial proliferation. It has been shown that disease severity is strongly dependent on the genetic background of mice. Inbred mouse strains, including C3H/HeJ and FVB/N are highly susceptible to *C. rodentium* infection associated with extensive tissue damage and increased lethality, while NIH:Swiss as well as C57BL/6J mice have been characterized to be more resistant. Therefore, we might suggest that *C. rodentium*-induced colitis in mice on C57BL/6N background was not an appropriate challenge to study consequences of CHOP under inflammatory conditions.

#### 5.4 Decrease in IEC regeneration is associated with enhanced inflammation

We could show that *Chop*<sup>IEC Tg/Tg</sup> mice were more susceptible to DSS-induced colitis associated with impaired re-epithelialization in the recovery phase. Regarding the nature of DSS-induced colitis, patchy distribution patterns of lesions made it impossible to evaluate whether mice were delayed in recovery due to defective proliferation instead of simply enlarged wounds. Enhanced inflammation has been observed in transgenic mice in response to short-term DSS treatment and in the recovery phase. Herein, increased inflammation seemed to be independent of CHOP-mediated pro-apoptotic signaling following gene expression profiles of colonic epithelial cells derived from 3 days DSS-treated mice and mice in the recovery phase. Even though a subset of genes were similarly regulated in *Chop*<sup>IEC Tg/Tg</sup> mice upon different DSS treatments, a correlation between CHOP overexpression and impaired IEC proliferation could not be determined. Nevertheless, we found differences in p38 MAP kinase activation in early inflammation (high) and recovery (low). Although we demonstrated that the effects of CHOP protein on both cell proliferation and migration were strongly dependent on its phosphorylation status, we could not find differences in banding patterns of CHOP protein in DSS-treated transgenic mice when compared to water-treated controls. However, upon short-term DSS treatment, wild-type mice displayed strongly decreased CHOP protein expression. Thereby, down-regulation of CHOP was dissociated from ER stress induction, increased expression of CHOP target genes *Gadd34* and *Ero1 $\alpha$*  as well as DSS-induced IEC apoptosis. We thus suggested that CHOP protein was reduced in order to enhance IEC proliferation in an early response to DSS-mediated IEC apoptosis. In this context, Araki et al. demonstrated that the onset of DSS-induced colitis was promoted by reduced epithelial turnover rates associated with enhanced apoptosis of IECs<sup>201</sup>. Along this line, we assumed that CHOP-mediated defects in IEC proliferation further enhanced the susceptibility to DSS-induced colitis in *Chop*<sup>IEC Tg/Tg</sup> mice. As a consequence, epithelial turnover is suggested to be further affected, consequently resulting in enhanced IEC apoptosis, elevated oxidative stress (*Ero1 $\alpha$* , *Gadd34*), and increased macrophage infiltration (Figure 64).

The effects of CHOP protein expression have been conversely described in disease-conditioning. Thereby, most insights into the functional role of CHOP were gained from studies on complete CHOP knockout mice<sup>167, 233</sup>. With regard to intestinal inflammation, *Chop*<sup>-/-</sup> mice exhibited less severe inflammation in response to DSS-induced colitis. Protection from colitis has been attributed to reduced numbers of mucosa infiltrating macrophages and decreased ROS production, which rather seemed to be in accordance to our data, but tissue-specific resolution remained elusive<sup>166</sup>.

**Figure 64. Proposed mechanisms underlying the increased susceptibility to DSS-induced colitis of *Chop*<sup>IEC Tg/Tg</sup> mice.**

(A) Short-term DSS treatment leads to the induction of IEC apoptosis, thus affecting epithelial turnover. Increased apoptosis is characterized by elevated oxidative stress indicated by up-regulation of Ero1 $\alpha$  and Gadd34 as well as macrophage infiltration into mucosal tissue. In early inflammation, CHOP protein is reduced in order to promote IEC proliferation. (B) Sustained CHOP protein expression results in decreased proliferation of IECs and impairs compensatory mechanisms to DSS-induced injury. As a consequence, epithelial turnover is further affected that in turn leads to enhanced IEC apoptosis associated with more elevated oxidative stress and enhanced numbers of mucosa-infiltrating macrophages.

Conclusively, we showed that CHOP-driven defects in IEC proliferation aggravated intestinal inflammation associated with changes in immune response. In this context, we demonstrated that decreased proliferation did not only delay epithelial regeneration, but resulted in impaired capacity to adapt to environmental changes.

## 5.5 Conclusion and perspectives

In conclusion, we showed that high CHOP protein expression in IECs could promote the development of IBD by affecting the epithelial proliferation. According to our data, we proposed that down-regulation of CHOP in UC reflected protective mechanisms underlying the regulation of epithelial proliferation in chronically inflamed tissue. Hence, it is questionable whether targeting the expression of CHOP is therapeutically significant in IBD. Since consequences of high CHOP protein expression in mice only became apparent in the onset of inflammation associated with mucosal tissue damage, CHOP might rather serve as an epithelial marker in estimating the risk of IBD.

Notably, prolonged IBD is highly associated with steadily rising risk for developing colorectal cancer<sup>234</sup>. Colorectal cancer is driven by cellular transformation that promotes persistent cell growth, which subsequently leads to tumor formation and gives rise to cancer cell development<sup>235, 236</sup>. Among others, it has been shown that CHOP down-regulation seems to be involved in the regulation of cellular transformation *in vitro*, while patients data strongly suggested that genetic alterations of CHOP contributes to the development of gastric cancer<sup>237-239</sup>. In this regard, recent studies demonstrated that induction of CHOP expression in human cancer cells led to cytotoxicity<sup>240-242</sup>. In accordance to our data, we strongly proposed that targeting CHOP protein expression is a potent therapeutic approach for the treatment of colorectal cancer. Taken together, our findings may suggest that therapeutic approaches could be considered for IBD patients in remission in order to inhibit uncontrolled epithelial proliferation and tumor risk.

## LIST OF FIGURES

Figure 1.	Disease-phenotype of the IBD subtypes CD and UC. ....	2
Figure 2.	Contribution of immune and inflammatory response to CD and UC. ....	3
Figure 3.	Model of UPR in restoration of cell homeostasis. ....	4
Figure 4.	ER stress-associated processes in intestinal inflammation. ....	5
Figure 5.	ER and mtUPR converge at the level of CHOP expression. ....	6
Figure 6.	Downstream signaling in ER UPR. ....	8
Figure 7.	Induction of CHOP mRNA expression during ER UPR according to Oyadomori et al. (2007). ....	10
Figure 8.	Regulatory mechanisms underlying the expression and transcriptional activation of CHOP. ....	12
Figure 9.	Pro-apoptotic signaling downstream of CHOP. ....	14
Figure 10.	Cell types in small and large intestine.....	16
Figure 11.	Canonical Wnt signaling leads to the expression of genes promoting cell cycle progression.....	17
Figure 12.	Generation of new mouse model <i>Chop</i> <sup>IEC Tg/Tg</sup> .....	33
Figure 13.	Breeding scheme for <i>Chop</i> <sup>IEC Tg/Tg</sup> mice and adequate wild-type controls.....	34
Figure 14.	Analysis of intestinal epithelial cell-restricted mRNA expression of Chop-HA. ....	35
Figure 15.	Transgene expression in IEC isolates from small and large intestine of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice and wild-type controls.....	35
Figure 16.	Expression of CHOP-HA on vertical and horizontal axis of the intestine.....	36
Figure 17.	Characterization of IEC fraction isolated from villus tip to the crypt.....	36
Figure 18.	Chromoendoscopic evaluation of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice. ....	37
Figure 19.	H&E stained intestinal sections of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice. ....	38
Figure 20.	Epithelial cell morphology of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice with an age of 12 weeks. ....	39
Figure 21.	IEC morphology of transgenic mice with an age of 24, 36, and 52 weeks. ...	40
Figure 22.	Protein overload upon transgene overexpression does not cause activation of NF-κB, MAP kinase, ER stress signaling, and mitochondrial stress signaling. ....	41
Figure 23.	Gene expression profiling of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice indicates changes in the inflammatory gene program. ....	42
Figure 24.	GO analysis regarding short distance biological process child terms revealed changes in the expression program associated with response to stimulus, death, and cell cycle. ....	45
Figure 25.	Reg3β expression in IECs of colon and distal ileum.....	47
Figure 26.	Validation of microarray data through the analysis of Reg3β expression. ....	47
Figure 27.	<i>C. rodentium</i> infection of 8 weeks old <i>Chop</i> <sup>IEC Tg/Tg</sup> mice and wild-type controls. ....	48

Figure 28.	Disease parameter in <i>C. rodentium</i> infection.....	49
Figure 29.	Reg3 $\beta$ expression in cecal tissue of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice and wild-type controls. ....	50
Figure 30.	Analysis of Reg3 $\beta$ expression in mice 25 days after <i>C. rodentium</i> infection. ....	50
Figure 31.	<i>Chop</i> <sup>IEC Tg/Tg</sup> mice are more susceptible to DSS-induced colitis. ....	51
Figure 32.	DSS-treated <i>Chop</i> <sup>IEC Tg/Tg</sup> mice reveal enhanced tissue pathology. ....	52
Figure 33.	Analysis of mucosa-infiltrating immune cells in 3 days DSS-treated mice....	53
Figure 34.	Analysis of CHOP and transgene expression in 3 days DSS-treated mice. ....	54
Figure 35.	CHOP target gene expression in 3d DSS-treated mice.....	55
Figure 36.	DSS-treated transgenic mice show an increase of cleaved caspase 3. ....	55
Figure 37.	<i>Chop</i> <sup>IEC Tg/Tg</sup> mice reveal delayed recovery from DSS-induced colitis.....	56
Figure 38.	Delayed recovery of transgenic mice associated with enhanced tissue pathology. ....	57
Figure 39.	Expression of endogenous and transgenic CHOP is not regulated upon recovery from DSS-induced colitis.....	57
Figure 40.	CHOP target gene expression in the recovery phase of DSS-induced colitis. ....	58
Figure 41.	Overview of CHOP-dependent gene expression upon DSS treatment. ....	59
Figure 42.	Hierarchical cluster analysis of DSS-treated mice. ....	60
Figure 43.	GO analysis of biological process terms regarding gene sets individually and commonly regulated upon DSS treatments. ....	64
Figure 44.	Gene expression profiles of WT and TG comparing 3d DSS and 5d DSS + 5d H <sub>2</sub> O treatment.....	66
Figure 45.	GO analysis of biological process terms regarding gene sets individually and commonly regulated in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice and wild-type controls, respectively. ....	66
Figure 46.	CHOP-HA undergoes proteasomal degradation in transiently transfected ptk6 cells. ....	70
Figure 47.	<i>In vitro</i> data indicate post-translational modification of CHOP-HA protein by phosphorylation.....	71
Figure 48.	CHOP-HA is post-translationally modified at p38 MAP kinase-specific phosphorylation sites ....	72
Figure 49.	Phosphorylation status of p38 MAPK upon 3 days 2% DSS and recovery from DSS-induced colitis.....	73
Figure 50.	Stably transfected ptk6 cell lines comparably express CHOP-HA and CHOP-HA [S78/81A].....	74
Figure 51.	CHOP-HA does not impact on epithelial integrity, but impairs epithelial cell proliferation.....	74
Figure 52.	CHOP-HA overexpression leads to impaired scratch closure in ptk6 cells.....	75
Figure 53.	High CHOP protein expression does not induce cell death in ptk6 cells ....	75

---

<i>Figure 54.</i>	Enhanced CHOP-HA and CHOP-HA [S78/81A] expression alters cell cycle progression in ptk6 cells. ....	76
<i>Figure 55.</i>	High CHOP protein expression does not affect Wnt signaling.....	77
<i>Figure 56.</i>	CHOP-HA overexpression has no effect on epithelial cell proliferation in jejunum and distal ileum of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice.....	78
<i>Figure 57.</i>	CHOP-HA overexpression in distal colon leads to reduced numbers of proliferative cells associated with decreased migration.....	79
<i>Figure 58.</i>	Wound healing is impaired in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice. ....	81
<i>Figure 59.</i>	Transgenic mice show delays in colonic epithelial regeneration. ....	82
<i>Figure 60.</i>	Delayed wound closure is associated with enhanced Vimentin production and reduced CD19+ immune cell infiltration.....	83
<i>Figure 61.</i>	Mucosal CD19+ cell infiltration in response to DSS treatment. ....	84
<i>Figure 62.</i>	Hypothetic inhibitory function of CHOP on cell cycle progression in colonic IECs.....	88
<i>Figure 63.</i>	Possible consequences of CHOP down-regulation under chronic inflammatory conditions. ....	91
<i>Figure 64.</i>	Proposed mechanisms underlying the increased susceptibility to DSS-induced colitis of <i>Chop</i> <sup>IEC Tg/Tg</sup> mice.....	94

## LIST OF TABLES

Table 1.	Primers used for site-directed mutagenesis of CHOP-HA.....	21
Table 2.	Primer list for qPCR analysis 1.....	21
Table 3.	Primer list for qPCR analysis 2.....	22
Table 4.	List of primary antibodies used in Western blotting.....	25
Table 5.	List of secondary antibodies used in Western blotting.....	26
Table 6.	Scoring criteria for disease activity index.....	31
Table 7.	Most highly regulated genes in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice are shown as TOP 10 up-regulated and TOP 10 down-regulated genes.....	43
Table 8.	Significantly regulated signal transduction pathways in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice ...	43
Table 9.	Significantly regulated child terms of the GO term biological process.....	44
Table 10.	Most highly regulated genes in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice regarding GO term <i>response to stimulus</i> are shown as TOP 10 up-regulated and TOP 10 down-regulated genes.....	45
Table 11.	Significantly regulated child terms defense response and response to wounding of the biological process term response to stimulus.....	46
Table 12.	Most highly regulated genes in 3 days DSS-treated <i>Chop</i> <sup>IEC Tg/Tg</sup> mice are shown as TOP 10 up- and down-regulated genes.....	61
Table 13.	Most highly regulated genes in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice upon recovery are shown as TOP 10 up- and down-regulated genes.....	61
Table 14.	Significantly regulated signal transduction pathways in DSS-treated <i>Chop</i> <sup>IEC Tg/Tg</sup> mice.....	62
Table 15.	Analysis of biological process terms in 3d DSS treatment.....	62
Table 16.	Analysis of biological process terms in DSS recovery phase.....	63
Table 17.	TOP 10 up- and down-regulated genes resulting from overlap analysis of gene sets significantly regulated in disease-free, 3d DSS-, and 5d DSS + 5d H <sub>2</sub> O-treated transgenic mice when compared to adequate wild-type controls.....	65
Table 18.	Most highly regulated individual genes in wild-type mice comparing gene expression profiles of 3d DSS-treated mice and mice in recovery are shown as TOP 10 up- and down-regulated genes.....	67
Table 19.	Most highly regulated individual genes in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice comparing gene expression profiles of 3d DSS-treated mice and mice in recovery are shown as TOP 10 up- and down-regulated genes.....	67
Table 20.	Most highly regulated overlapping genes in wild-type mice comparing gene expression profiles of 3d DSS-treated mice and mice in recovery are shown as TOP 10 up- and down-regulated genes.....	68
Table 21.	Most highly regulated overlapping genes in <i>Chop</i> <sup>IEC Tg/Tg</sup> mice comparing gene expression profiles of 3d DSS-treated mice and mice in recovery are shown as TOP 10 up- and down-regulated genes.....	68

## CURRICULUM VITAE

### Personal data

**Nadine Waldschmitt**

M.Sc. Molecular Biotechnology (TUM)

Birth 10-24-1979

### Education

12/2009 – 11/2013

**PhD candidate,**

Dissertation topic: Tissue-specific overexpression of UPR-related C/EBP homologous protein impairs mucosal repair in *Chop*<sup>IEC Tg/Tg</sup> mice

*Chair of Nutrition and Immunology, Technische Universität München (TUM), Prof. Dr. Dirk Haller*

10/2007 – 09/2009

**Master of Science, Molecular Biotechnology (TUM)**

passed with high distinction (1.0)

Thesis topic: Examination of oxidative stress resistance of lactic acid bacteria in starter cultures

*Chair of Technical Microbiology, TUM, Prof. Dr. Rudi F. Vogel*

10/2004 – 09/2007

**Bachelor of Science, Molecular Biotechnology (TUM)**

passed with merit (1,6)

Thesis topic: Role of GM-CSF in bovine uteri during implantation

*Chair of Molecular Physiology, TUM, Prof. Dr. H.H. Meyer*

08/2000 – 12/2002

**Biological laboratory technician, Paul-Ehrlich Institut,**

*Langen in cooperation with Merck KGaA, Darmstadt*

awarded for the best exam in 2002, IHK Offenbach

10/1990 – 07/1999

**Abitur, Immanuel-Kant Gymnasium, Tuttingen**

### Work experience

01/2014 – current

**Postdoctoral researcher, NODS-Like receptors in infection and immunity, Pasteur Institut Lille, Dr. Mathias Chamaillard**

12/2009 – 11/2013

**PhD candidate, Chair of Nutrition and Immunology, TUM, Prof. Dr. Dirk Haller**

02/2008 – 10/2008

**Research Associate (20 hours/week),**

*Chair of Molecular Physiology, TUM,*

*Prof. Dr. H.H. Meyer*

04/2006 – 01/2007

**Lab technician (20 hours/week), Chair of Molecular**

*Physiology, TUM, Prof. Dr. H.H. Meyer*

10/2004 – 07/2005

**Student assistant, Sirenade Pharmaceuticals, Martinsried**

01/2003 – 09/2004

**Lab technician, SiREEN AG, Martinsried**

### Additional education

10/2012 – 03/2013

**Lecture Quality Management (distance study) with QMB (TÜV) certification,**

*Internationales Hochschulinstitut Zittau, Prof. Dr. R. Förster*

08/2007 – 12/2007

**Practical training** (4 month), *Chair of Reproductive Physiology, Universidad de Murcia, Spain, Prof. Dr. Pilar Coy, Fellowship Erasmus Praktikum*

2008

**Ausbilder-Eignungsschein** (AEVO)

2003

**Trained assistant for molecular biology, molecular medicine, and gene technology**, *Rheinisches Bildungszentrum e.V. Köln, Institute for Biology and Medicine*

### Activities

- voluntary work Lebenshilfe, e.V., Freising (2009-2010)
- participation in E-Mentoring-Program CyberMentor for girls and women with scientific interests, University of Regensburg (2010-2012)

Freising, 2014

## PUBLICATIONS AND PRESENTATIONS

### Peer-reviewed original manuscripts

Waldschmitt N, Berger E, Rath E, Sartor RB, Weigmann B, Heikenwalder M, Gerhard M, Janssen KP, Haller D. *C/EBP homologous protein inhibits tissue repair in response to gut injury and is inversely regulated with chronic inflammation*. MUCOSAL IMMUNOLOGY (2014) 7 (6): 1452-1466

Mapesa JO, Waldschmitt N, Schmoeller I, Blume C, Hofmann T, Mahungu S, Clavel T, Haller D. *Catechols in caffeic acid phenethyl ester are essential for inhibition of TNF-mediated IP-10 expression through NF- $\kappa$ B-dependent but HO-1-and p38-independent mechanisms in mouse intestinal epithelial cells*. MOLECULAR NUTRITION & FOOD RESEARCH (2011) Volume: 55 Issue: 12 Pages: 1850-1861

Ulbrich SE, Frohlich T, Schulke K, Englberger E, Waldschmitt N, Arnold GJ, Reichenbach HD, Reichenbach M, Wolf E, Meyer HHD, Bauersachs S. *Evidence for Estrogen-Dependent Uterine Serpin (SERPINA14) Expression During Estrus in the Bovine Endometrial Glandular Epithelium and Lumen*. BIOLOGY OF REPRODUCTION (2009) Volume: 81 Issue: 4

### Published abstracts

Waldschmitt N, Rath E, Berger E, Haller D. *Expression of C/EBP Homologous Protein in Intestinal Epithelial Cells is Not Associated With the Development of Chronic Inflammation: A Transgenic Approach*. Gastroenterology (2012) Volume: 142 Issue 5, Supplement 1 Page S-124

Schulke K, Groebner AE, Waldschmitt N, Ulbrich SE, Meyer HH. *Increased fibroblast growth factor 2 protein in the bovine endometrium coincides with beginning trophoblast elongation during preimplantation development*. REPRODUCTION IN DOMESTIC ANIMALS (2009) Volume: 44, Pages 33-33

Grullon L, Saavedra MD, Waldschmitt N, Coy P. *Effect of Plasminogen on Zona Pellucida Resistance to Proteolysis and In Vitro Fertilization Results in Pig*. REPRODUCTION IN DOMESTIC ANIMALS (2008) Volume: 43, Supplement: 5 Pages 80-80

### Oral presentations

Waldschmitt N, Berger E, Rath E, Weigmann B, Janssen K-P, Haller D. *Tissue-specific overexpression of UPR-related C/EBP homologous protein impairs mucosal repair in Chop<sup>IEC Tg/Tg</sup> mice*. 50. Wissenschaftlicher Kongress der Deutschen Gesellschaft fur Ernahrung (German Nutrition Society), March 20-22, 2013, Bonn, Germany

Waldschmitt N, Rath E, Berger E, Haller D. *Association of C/EBP homologous protein in intestinal epithelial cells with the development of chronic inflammation: a transgenic approach*. 5th Seon Conference (German Society for Hygiene and Microbiology), June 15-17, 2012, Kloster Seon, Germany

Waldschmitt N, Rath E, Berger E, Haller D. *Expression of C/EBP Homologous Protein in Intestinal Epithelial Cells is Not Associated With the Development of Chronic Inflammation: A Transgenic Approach*. Digestive Disease Week, May 19-22, 2012, San Diego, US

### Poster presentations

Waldschmitt N, Berger E, Rath E, Sartor RB, Weigmann B, Gerhard M, Janssen K-P, Haller D. *Tissue-specific overexpression of UPR-related C/EBP homologous protein impairs mucosal tissue repair*. 21st United European Gastroenterology Week, 12-16 October 2013, Berlin, Germany (Poster of Excellence)

Waldschmitt N, Berger E, Heupel E, Rath E, Boekschoten MV, Riedel CU, Weigmann B, Niess JH, Janssen K-P, Haller D. *Tissue-specific overexpression of UPR-related C/EBP homologous protein impairs mucosal tissue repair*. 10<sup>th</sup> NuGOweek, 9-12 September 2013, Freising-Weihenstephan, Germany

Waldschmitt N, Berger E, Heupel E, Rath E, Boekschoten MV, Riedel CU, Weigmann B, Niess JH, Janssen K-P, Haller D. *Tissue-specific overexpression of UPR-related C/EBP homologous protein impairs mucosal tissue repair*. 16<sup>th</sup> International Congress of Mucosal Immunology, 17-20 July 2013, Vancouver, Canada

Waldschmitt N, Berger E, Rath E, Haller D. *Association of C/EBP homologous protein in intestinal epithelial cells with the development of chronic inflammation: a transgenic approach*. 50. Wissenschaftlicher Kongress der Deutschen Gesellschaft für Ernährung (German Nutrition Society), March 20-22, 2013, Bonn, Germany

Berger E, Yuan D, Waldschmitt N, Simonavicius N, Janssen K-P, Heikenwälder M, Haller D. *Tissue-specific knock out mouse models reveal a crucial role of mitochondrial HSP60 for maintaining homeostasis in intestinal epithelial cells*. 50. Wissenschaftlicher Kongress der Deutschen Gesellschaft für Ernährung (German Nutrition Society), March 20-22, 2013, Bonn, Germany

Waldschmitt N, Berger E, Rath E, Haller D. *The Ambivalent Role of CHOP Signaling in IBD*. 49. Wissenschaftlicher Kongress der Deutschen Gesellschaft für Ernährung (German Nutrition Society), March 14-16, 2012, Freising-Weihenstephan, Germany

Waldschmitt N, Berger E, Rath E, Haller D. *Transgenic and knock-out mouse models – A tool to study inflammatory stress responses*. 4th Seeon Conference (German Society for Hygiene and Microbiology), April 15-17, 2011, Kloster Seeon, Germany

## **Grants**

Travel Grant, GlaxoSmithKline foundation  
(21st United European Gastroenterology Week, 12-16 October 2013, Berlin, Germany)

Erasmus Placement Scholarship, 2007  
(four-month research period at the University of Murcia, Spain)

Vocational Training Programme for the Highly Talented (Begabtenförderung Berufliche Bildung), Industrie- und Handelskammer Darmstadt, 2003

## ERKLÄRUNG

Hiermit erkläre ich, dass ich die vorliegende Doktorarbeit selbstständig angefertigt habe. Es wurden nur die in der Arbeit ausdrücklich benannten Quellen und Hilfsmittel benutzt. Wörtlich oder sinngemäß übernommenes Gedankengut habe ich als solches kenntlich gemacht.
