Investigation of Ni/ZrO₂ catalysts for the hydrodeoxygenation of microalgae oil

Sebastian Dieter Foraita

Vollständiger Abdruck der von der Fakultät für Chemie der Technischen Universität München zur Erlangung des akademischen Grades eines

Doktors der Naturwissenschaften (Dr. rer. nat.)

genehmigten Dissertation.

Vorsitzender: Univ.-Prof. Dr.-Ing. Kai-Olaf Hinrichsen

Prüfer der Dissertation:

1. Univ.-Prof. Dr. Johannes A. Lercher
2. Univ.-Prof. Dr. Thomas Brück

Die Dissertation wurde am 13.02.2017 bei der Technischen Universität München eingereicht und durch die Fakultät für Chemie am 13.03.2017 angenommen.

„Mit meinem Gott überspringe ich Mauern.“ Psalm 18,30

Acknowledgment

It has been a long way and a hard piece of work. There are many people, who supported me all the way or significant parts of it and contributed to this thesis. I am deeply grateful and want to particularly thank them, here.

First of all I want to express my sincere gratitude to Johannes (Prof. Dr. Johannes A. Lercher) giving me an opportunity with this interesting topic in your high level and famous catalysis group. Thank you for teaching me well and your critical guidance with your broad knowledge in catalysis and science. I enjoyed the international style and experience of your group.

I thank Prof. Dr. Thomas Brück as my second examiner and project leader of the Algen-FlugKraft project supported by Bavarian Ministry of Economic Affairs and Media, Energy and Technology (“Bayerisches Staatsministerium für Wirtschaft und Medien, Energie und Technologie”) and Bavarian State Ministry of Education, Science and the Arts (“Bayerisches Staatsministerium für Bildung und Kultus, Wissenschaft und Kunst”).

I want to thank Chen, Eszter and Yue for their co-supervision as responsible subgroup leaders. Thank you for the help in planning experiments, discussing results and shaping paper manuscripts and presentations.

Many and special thank deserve to Gary (Prof. Gary Haller) for our fruitful collaboration, discussions, your patience and the additional guidance. I appreciate your advice a lot.

I am grateful to Don (Donald M. Camaioni) and John L. Fulton from Pacific Northwest National Laboratory (PNNL) for co-supervision, EXAFS-lessons, scientific discussions, good collaboration, overwhelming hospitality and the great time at the Advanced Photon Source in Argonne, IL and the PNNL in Richland, WA.

I appreciate the feedback and support of Andy, Oliver, Maricruz, Erika and André in daily lab situations and especially in our group’s seminars.

I want to thank Dipl.-Min. Katia Rodewald for teaching me how to operate the High Resolution SEM and sharing her extensive experience with me and Dr. Gabriele Raudaschl-Sieber for solid state ^{29}Si -NMR measurements.

Nothing would work without Xaver – I appreciate your help and the support of Martin and Andreas. My work would not have been possible without Steffi, Uli, Bettina and Karen managing everything from the administrative side.

Many special thanks deserve to my dear office colleagues Xianyong, Eva, Tobias, Stanislav, Jeongnam, Marco, Yang Song, Takaaki and Christoph for the good atmosphere and being the first place to go for scientific discussions and other problems. I keep my former colleagues Christian, Sebastian G., Sebastian M., Navneet, Lisl, Max, Jenny, Daniela, Jiayue, Claudia, Robin, Stefan, Anastasia, Bo, Baoxiang, Monica, Steffi, Linus and Sonja in good memory for their support and the good collaboration especially in the beginning. Additionally, I thank the remaining members of TC II Ferdinand, Martina, Andreas, Kai, Daniel, Peter, Moritz, Sylvia, Manuel, Edith, Yu, Matthias, Udishnu and Yuanshuai for working with you. I thank Zizwe, Aleksei and Pinghong from PNNL for our fruitful cooperation as well.

I thank my former classmates David, Markus, Julia, Sabrina, Sabine and Alex for the interdisciplinary discussions and support.

Thanks to my interested, motivated, skilled and hardworking students Sebastian E., Tommy, Thomas, Christian, Zhe Liang, Lorenz, Patrick, Christoph, Julia, Johannes, My, Ferdinand, Sebastian H., Janosch and Matthew I did not have to do all the work on my own. I benefited a lot from teaching you and I like to see that you are carrying on so well.

Last but not least, I want to thank my family for their support, open ear and refocusing to the important things especially during the toughest times.

Abstract

The catalytic properties of metallic Ni supported on *monoclinic* and *tetragonal* ZrO₂ for hydrodeoxygenation of stearic acid was investigated. Due to a higher concentration of oxygen defect sites, *monoclinic* ZrO₂ supported catalysts were three times more active, because the adsorption of carboxylic acid was enhanced. An even higher activity was achieved by incorporation of SiO₂ into the ZrO₂ lattice. Those materials form novel nano-layers possessing Brønsted acid sites and high specific surface area.

Zusammenfassung

Die katalytischen Eigenschaften von metallischem Ni geträgert auf *monoklinem* und *tetragonalem* ZrO₂ wurden für die Hydrodeoxygenierung von Stearinsäure untersucht. Durch die höhere Konzentration von Sauerstoffdefektenstellen waren die auf *monoklinem* ZrO₂ geträgerten Katalysatoren dreimal aktiver, da die Adsorption der Carboxysäure erhöht wurde. Eine noch höhere Aktivität konnte durch den Einbau von SiO₂ in das ZrO₂ Gitter erreicht werden. Diese Materialien bilden neuartige Nanoschichten aus, die Brønsted-Säure-Zentren und eine hohe spezifische Oberfläche besitzen.

Chapter 1

Introduction and general background

Recent global political events led to an interim drop in crude oil price (29 \$/barrel for Brent in January 2016)¹, pretending that the necessity to displace fossil fuels is less urgent. However, extreme weather events, even in moderate climate regions, are commonly agreed to be related to climate change and the increase of the average temperature worldwide. This rise of the mean global temperature is caused by the emissions of greenhouse gases (GHG).² The European Union (EU) has decided to restrict the increase of the mean global temperature to 2 °C above pre-industrial levels by mitigating the emissions of GHG by 20%, increase the share of renewable energy to 20% and raise energy efficiency by 20% until 2020 compared with the level from 1990 (Europe 2020 strategy targets).³ The limit of 2 °C increase was adapted by the “Paris Agreement” under the United Nations Framework Convention on Climate Change.⁴ CO₂ is the most abundant GHG, which is predominantly generated by the combustion of fossil fuels.⁵ With a share of 18%, the transportation sector is still the second highest contributor of GHG-emissions in Germany (**Figure 1-1**),⁶ consuming gasoline, diesel, kerosene and heavy fuel oil originated from fossil oil. Renewable fuels (*i.e.* biofuels) are the most promising approach to overcome these problems because they are considered as CO₂-neutral.⁷ This means that the emitted amount of CO₂ by combustion of those biofuels is equal to the sequestered amount of CO₂, which is captured *via* photosynthesis during growth of the respective plant of origin.⁸

In a first generation of biofuels, ethanol is produced by fermentation of glucose from edible plants (*e.g.* corn and sugar cane). The second generation of biofuels is fatty acid methyl ester (FAME), known as bio-diesel, produced from vegetable oil (sunflower oil, palm oil, rapeseed oil) *via* transesterification with methanol. Those plant sources of the vegetable oil, however, compete with arable land necessary for food production and consume fresh water. Additionally, bio-diesel bears several technical and practical disadvantages compared to conventional diesel. Microalgae, however, are envisioned as a renewable source for the production of third generation biofuels, converted to hydrocarbon diesel (*i.e.* *green diesel*) by hydrodeoxygenation.⁹

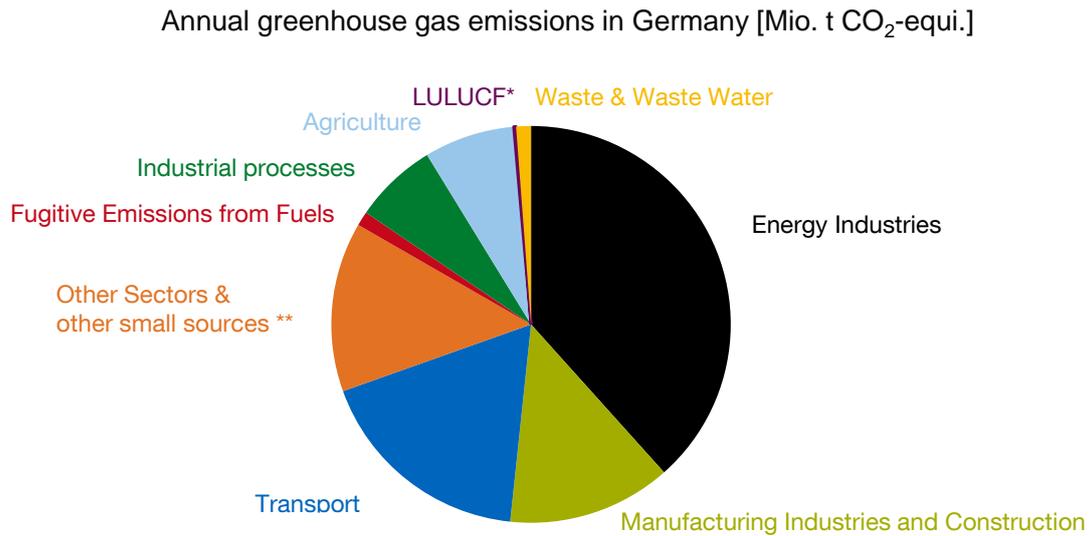

Figure 1-1. Annual greenhouse gas emissions in Germany in million tons CO₂ equivalent based on data from ⁶: * Land use, land-use change and forestry; ** common reporting format

1.1 Microalgae – a renewable source of triglycerides for biofuels

Microalgae are either prokaryotic or eukaryotic photosynthetic microorganisms,¹⁰ directly converting sunlight, CO₂ and nutrients into O₂ and biomass (*i.e.* mainly triglycerides, proteins and saccharides).¹¹ **Figure 1-2** shows a general molecular formula of a triglyceride representing microalgae oil. The photosynthetic rates of microalgae are higher than those of terrestrial plants and they capture 10% of incident solar energy.⁵ Reaching up to 70 wt% of dry biomass,¹² the oil content is extraordinarily high and the growth rates are 10-20 times faster than conventional terrestrial oil plants (*e.g.* rapeseed, palm and sunflower).^{10, 13} In contrast to the first- and second generation of biofuels, the third generation is advantageous from an ethical point of view, because the production of microalgae is not competing with agriculture, as no arable land is required.^{10, 13-14} In general, microalgae are highly adaptable to extreme living conditions.^{9b, 15} Halophile microalgae tolerate saline concentrations of seawater and above, which is a clear advantage at places with high sunlight radiation, often related to short fresh water supply that is more urgently needed for survival of the domestic population. In addition to that, salt water as growing media is more resistant against contamination.¹⁴ The ideal setup for an integrated production of microalgae at large scale uses wastewater as N-source¹⁴ and flue gas from fossil fuel power plants as CO₂-source.^{10, 13}

When the algae is under nutrient stress (limitation of nitrogen or phosphorous), osmotic stress, radiation, (extreme) pH, temperature, heavy metals or other chemicals, the cell produces triglycerides. Those lipids provide an energy storage for the cell, enabling the microalgae to endure unfavorable environmental conditions. This is called *lipid induction*. Among those, the limitation of N-source is the most widely applied technique leading to the accumulation of storage compounds (*i.e.* triglyceride) within the algae cell.¹⁶ In order to obtain the desired triglyceride out of the cell, it has to be extracted, which is economically and energetically the most crucial step in the concept of bio-fuels from microalgae. Methods for cell disruption includes high-pressure homogenization, bead beating, ultrasonication (micro-cavitation), treatment with microwaves, hydrothermal treatment, supercritical fluid extraction, solvent extraction and sulfuric acid treatment.¹⁷

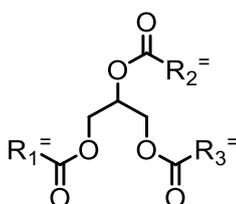

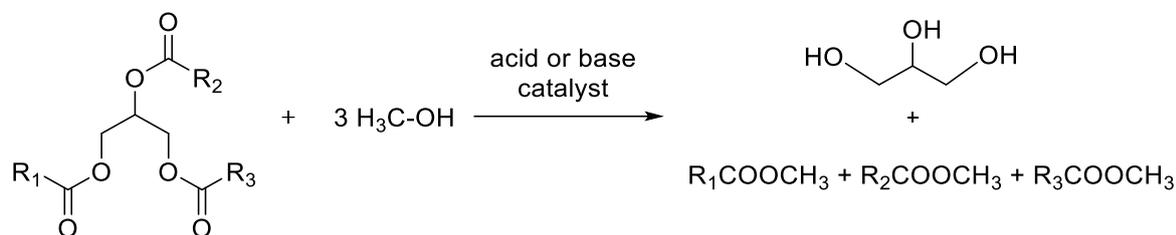

Figure 1-2. General molecular formular of a triglyceride – R₁, R₂ and R₃ are representing saturated or unsaturated fatty acid residues.

1.2 Routes of triglyceride conversion

Transesterification with alcohol is the most conventional route in upgrading triglycerides from vegetable oil, algae oil or waste fats that has been applied commercially so far (**Scheme 1-1**). The composition of a representative microalgae oil and the distribution of fatty acid residues is compiled in **Table 1-1**. Depending on the availability and economic considerations,^{5, 18} the most common product is fatty acid methyl ester (FAME), usually blended with petroleum diesel and sold as Biodiesel.¹⁹ Chemically, however, this Biodiesel is explicitly different to petroleum diesel, leading to several disadvantages. Due to the (relatively) high oxygen content, the energy density is lower compared to petroleum diesel. The flow quality at low temperatures is poor and the thermal- and oxidation stability is low,

requiring technical solutions necessary that go together with abrasive wear of the engine and parts thereof.²⁰

Scheme 1-1. Transesterification of triglyceride with methanol leading to glycerol and fatty acid methyl ester (FAME).

[b] The nomenclature shows the number of carbon atoms and the number of C=C double bonds: *e.g.* the alkyl chain of the present fatty acid contains 14 C atoms and no double bonds (C_{14:0}).

This thesis, however, shall deal with a more sustainable approach, focusing on non-esterified renewable diesel (NERD) also referred to as *Green Diesel*. As stated above, the relatively high oxygen content of triglycerides and FAME is disadvantageous and oxygen has to be removed directly from the triglyceride to obtain long chain alkanes in the diesel range (C₉-C₂₂).²¹ Similar to the removal of nitrogen through hydrodenitrogenation (HDN) and sulfur through hydrodesulfurization (HDS), oxygen can be removed *via* hydrotreating catalysts using H₂.²² This removal of oxygen from an organic molecule with H₂ is called hydrodeoxygenation (HDO). Suitable catalysts are supported or unsupported transition metal sulfides (*e.g.* NiMo and CoMo sulfide)²³ which are already applied commercially for this purpose and offer the advantage of using an existing infrastructure.²⁴ With these catalysts, triglycerides can be converted to longchain and unbranched alkanes in the diesel range at process conditions of 10-200 bar H₂ at 350-450 °C.²⁵ This renewable diesel has high cetane numbers in the range of 70-90.²⁶ Transition metal sulfides catalysts, however, are not

ideal because they deactivate in such oxygen rich (*i.e.* sulfur free) feeds and contaminate the product with sulfur leached from the catalyst by a reverse Mars-van-Krevelen-mechanism.²⁷

In order to overcome this drawback, sulfur free catalysts were developed. Catalytic deoxygenation of triglycerides and fatty acids was achieved with Ru, Pd, Pt, Re, Ir, Os, Mo, Rh and Ni supported on SiO₂, MgO, C, Al₂O₃ or zeolites (HBEA, H-ZSM-5).²⁸ Among those, Pd and Pt show the highest conversion of stearic acid and high selectivity towards *n*-heptadecane. Additionally and in contrast to hydrotreating, catalytic deoxygenation requires lower reaction temperature (250-300 °C),^{28b} provides higher selectivity of the corresponding alkane and has lower consumption of H₂.^{9b, 28a, 29}

Scheme 1-2. Proposed reaction network for hydrogenation and hydrogenolysis of microalgae oil and the hydrodeoxygenation of stearic acid, showing the decarbonylation route towards *n*-heptadecane (C₁₇), dehydration/hydrogenation to *n*-octadecane (C₁₈) and reversible esterification towards stearyl stearate.

Starting with microalgae oil as a typical triglyceride (**Figure 1-2**), the deoxygenation to alkanes is carried out in a reaction sequence (**Scheme 1-2**). In a first step, the double bonds of the unsaturated fatty acid residues are hydrogenated (**Eq. 1**) and the ester bonds of the fatty acids with the glycerol backbone are cleaved *via* hydrogenolysis resulting in the formation of propane and carboxylic acid (**Eq. 2**). Those fatty acids (*e.g.* stearic acid) are hydrogenated (**Eq. 3**) leading to the corresponding aldehyde (octadecanal), that is equilibrated with alcohol (1-octadecanol) *via* hydrogenation-dehydrogenation (**Eq. 4**).³⁰ The de-

oxygenation of the aldehyde takes place *via* decarbonylation (-CO), without a net consumption of H₂ (**Eq. 5**), whereas the alcohol can be deoxygenated by Brønsted-acid-catalyzed dehydration with subsequent hydrogenation over transition metal (**Eq. 6 + Eq. 1**).³¹ Alternatively, the fatty acid can directly undergo decarboxylation (-CO₂, **Eq. 7**) on Pd/SiO₂ or hydrodeoxygenation (-H₂O, **Eq. 8**) on Pd/NbOPO₄.³² Both decarbonylation and decarboxylation lead to the loss of one carbon atom, whereas the product formed by dehydration-hydrogenation or hydrodeoxygenation has the same carbon number as the substrate carboxylic acid. Therefore, decarbonylation and decarboxylation reaction consume less H₂, but the carbon economy is lower. The long chain alkane obtained *via* hydrodeoxygenation from microalgae oil is chemically indistinguishable from petroleum based diesel fuel.³³

However, precious metals are costly and therefore their feasibility for industrial application is limited. Recently the quantitative conversion of both stearic acid and crude microalgae oil (without purification) was achieved with supported Ni catalysts, which is more economical.^{31, 34} However, H-ZSM-5 (Si/Al = 45) used as a support there, lead to severe cracking, because of the high concentration of Brønsted acid sites. Consequently, those products do not fit in the diesel range. Obviously, in addition to the catalytically active metal, the support has significant contribution to the catalytic performance. After investigating a series of oxidic supports including SiO₂, Al₂O₃, TiO₂, CeO₂ and ZrO₂, ZrO₂ turned out to be the best one, enhancing the catalytic activity synergistically.³⁰

In presence of a reducible oxide (*i.e.* ZrO₂), oxygen vacancies of ZrO₂ facilitate the concerted adsorption of stearic acid and H₂ activation (**Figure 1-3**). The oxygen vacancy from the transition metal oxide is (re)filled with an oxygen from the carboxylic group of the acid.³⁵ In line with that, a surface carboxylate is formed and α -hydrogen is abstracted forming a ketene intermediate,³⁶ which is in turn hydrogenated to aldehyde on Ni and subsequently decarbonylated to *n*-heptadecane and CO.³⁷ Therefore, the oxygen vacancy is an active site for the first hydrogenation/deoxygenation step and anchoring the reactant molecule. To regenerate the oxygen vacancy of ZrO₂, the abstracted α -hydrogen and the proton from the carboxylic acid OH-group recombine with oxygen bound to ZrO₂ forming H₂O. Hence, the selective hydrogenation of fatty acid to aldehyde takes place *via* a Mars-van-Krevelen-mechanism.³⁸ The bond strength of the metal oxide is crucial and has to be balanced that facilitates both the creation of the vacancy and the adsorption of the carboxylic

groups in fatty acids.³⁵ Together, the redundancy function of Ni and ZrO₂ enhances the overall hydrodeoxygenation of stearic acid.

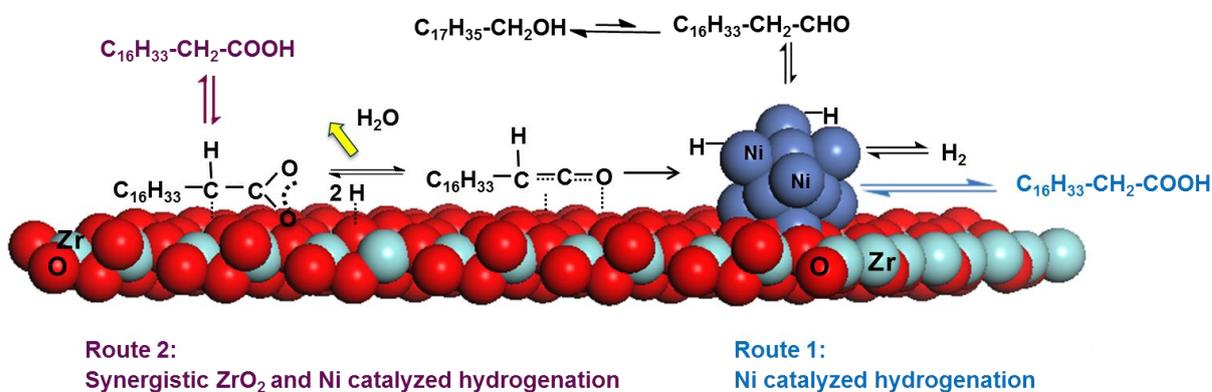

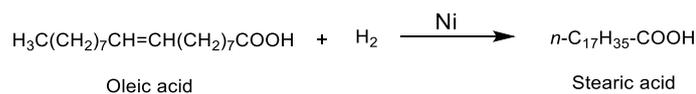

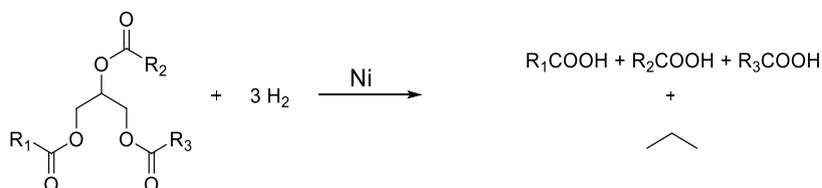

Figure 1-3. Proposed reaction mechanism of the hydrogenation of stearic acid to octadecanal by synergistic catalysis over Ni/ZrO₂ in the presence of H₂ (adapted from ^{37a} with permission of John Wiley and Sons).

The important reactions during the hydrodeoxygenation process are summarized in **Eq. 1-8**:

1.3 ZrO₂ – a multifunctional catalyst support

1.3.1 General properties of ZrO₂

Among other disciplines, ZrO₂ is highly appreciated especially in heterogeneous catalysis *inter alia* due to its excellent mechanical properties, porosity, low thermal conductivity, stable surface area at high temperature, high resistance to corrosion and high melting point (2680 °C).³⁹ Additionally, ZrO₂ uniquely possesses acid- and base sites as well as oxidizing and reducing properties.⁴⁰

1.3.2 Crystal phases of ZrO₂

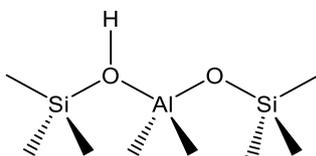

Zirconia occurs in four polymorphs,⁴¹ *i.e.* *monoclinic* (*m*-) at ambient temperature until 1170 °C, *tetragonal* (*t*-) between 1170 and 2370 °C, *cubic* (*c*-) until the melting point (2370-2680 °C) and orthorhombic forming only at elevated pressures (**Scheme 1-3**).⁴² At ambient conditions, *monoclinic* is the predominant phase and represented by the mineral Baddeleyite in nature. *Tetragonal*-phase, however, has the highest mechanical strength and is more suitable for ceramic applications.^{42d, 43} Ideally, the crystal structure of *c*-ZrO₂ is based on a CaF₂ lattice type,⁴⁴ where Zr is eightfold coordinated with oxygen and every O is tetrahedrally coordinated by Zr. In *t*-ZrO₂, the crystal lattice shows only small deviations from the ideal CaF₂-structure and still an eightfold coordination of Zr.⁴⁵ In contrast to that, *m*-ZrO₂ is considerably more distorted with respect to the ideal CaF₂-structure and the Zr⁴⁺ cation is sevenfold coordinated with oxygen, whereas O is either trigonally or tetrahedrally coordinated by Zr. Detailed crystallographic structures are extensively discussed and visualized in literature.⁴⁴⁻⁴⁶

Scheme 1-3. Phase transition of ZrO₂ as a function of temperature.

1.3.3 Generation of Lewis- and Brønsted acid sites on the surface of ZrO₂

Pure ZrO₂ almost exclusively shows Lewis acidic properties, as it was shown by IR spectroscopy of adsorbed pyridine that is coordinately bound to the surface of ZrO₂, whereas Brønsted acid sites are absent.⁴⁷ By mixing with another oxide, Brønsted acid sites can be generated on ZrO₂. According to **Thomas' model**, a cation of a metal that is isomorphously substituted into a metal oxide structure comprised of a cation with higher charge (*e.g.* Al³⁺ into SiO₂), would need a balancing charge, which is most likely a proton.⁴⁸ That means, Al adapts the tetrahedral coordination of oxygen and the resulting charge deficit has to be compensated by a proton associated with it. This proton is acidic (**Scheme 1-4**).

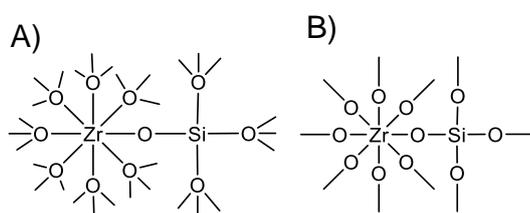

Scheme 1-4. Schematic representation for the generation/formation of an acidic proton in a mixed SiO₂-Al₂O₃ oxide.⁴⁹

However, this model does not explain the generation of acidity for binary metal oxides (chemically bonded), when both cations have the same charge (*e.g.* SiO₂-ZrO₂). **Tanabe et al.** elaborated the model, stated above, taking into account the coordination numbers CN of the oxygen anion and both of the cations.⁵⁰ It is based on two fundamental assumptions:

- i) They hypothesized that in a model structure, the coordination number of each metal cation is maintained as in its pure oxide.
- ii) On the contrary, all oxygen anions of a binary metal oxide retain the coordination number of the major (oxide) component.

A charge imbalance formed by this is generating either LAS or BAS. A positive excess charge is generating a LAS, whereas a negative excess charge is the reason for a BAS. The example SiO₂-ZrO₂ is shown in **Scheme 1-5**. For ZrO₂-rich mixed oxides, the four positive charges of Si are distributed to four bonds (+4/4) and two negative charges of an oxygen anion are shared by four bonds (-2/4), *i.e.* the coordination of oxygen in ZrO₂, according to assumption i) in Tanabe's hypothesis. The charge difference for one bond is $+1 - \frac{1}{2} = +\frac{1}{2}$

and $4 \cdot \left(+\frac{1}{2}\right) = +2$ for the whole valence unit (**Scheme 1-5, A**). Therefore, Lewis acidity is predicted (electron acceptor), which is in agreement with experimental observations.⁵¹ If the major part of the binary oxide is SiO₂ (**Scheme 1-5, B**), four positive charges of Zr are distributed among eight bonds $\left(+\frac{4}{8}\right)$, while two negative charges are shared between two bonds $\left(-\frac{2}{2}\right)$. The result for the whole valence unit is $8 \cdot \left(+\frac{1}{2} - 1\right) = -4$. Negative excess charge requires a proton to balance it and thus imparts Brønsted acidity.⁵²

Scheme 1-5. Model structure of SiO₂-ZrO₂ mixed oxide unit considering assumptions i) and ii). **A)** ZrO₂-rich binary oxide (containing LAS), **B)** SiO₂ is the major component (containing BAS).

However, this model is lacking an explanation for the simultaneous presence of both BAS and LAS at the same material in most of the binary oxides. This can be explained by the concept of micro-regions,⁵³ where inhomogeneities of the mixed oxides being responsible for either of the oxide being the major or minor part, respectively. Nevertheless, they are assuming that the coordination number of the cation is not changing in the mixed oxide.^{50, 53} This is not the case for SiO₂-TiO₂, as demonstrated experimentally by EXAFS and XRD.⁵⁴ Miller and Ko are generally following Tanabe's model explaining the generation of BAS and LAS and mention the heterolinkage Si-O-Zr as the acid site. Additionally, they point out that Zr enters the SiO₂-network maintaining its coordination number of 7 or 8.⁵²

Kataoka and Dumesic also use valence and coordination of the cation to explain the generation of acidity in binary metal oxides, derived from Paulings electrostatic valence rule.⁵⁵ Different valence and coordination number of the cations generate undersaturated oxygen, that are compensated by Si-O-Zr bridges bearing a formal negative charge as in the case of SiO₂-Al₂O₃.⁵⁶ Therefore, an acidic proton, located at the Si-O-Zr bond, is necessary to compensate the negative charge at the bridging oxygen.⁵⁶ Formally, this can be imagined like Thomas' model (**Scheme 1-4**, page 10).

1.4 Bimetallic catalysts for hydrodeoxygenation

In the previous chapter 1.2 (page 3), sulfur free catalysts were presented for the hydrodeoxygenation of triglycerides and fatty acids. Unfortunately, the most active and selective metals (*i.e.* Pd and Pt) are precious metals and rather expensive. Base metals (*e.g.* Ni, Co, Cu, Fe, Mo), as a more economic alternative, suffer from lower activity, stability, recyclability and selectivity, especially under the circumstances of biomass feeds with high chemical complexity.⁵⁷ Therefore, the combination of two active metals is a promising option to optimize such catalysts in terms of catalytic parameters, mechanical properties and economic feasibility.

Combinations of Pt, Pd and Ru with Ni, Co, Cu, Fe and Mo are successfully investigated in the de-functionalization of sugar monomers and polysaccharides (especially cellulose), glycerol, hemicellulose, furfural, fatty acid esters, carboxylic acids, lignin and derivatives thereof.⁵⁸

The advantageous effect of the second metal is that it helps reducing the first one or keep it reduced.⁵⁹ Further, there are geometric effects altering the geometry of the active site, electronic effects by electron transfer between metals,^{58d 60} stabilizing effects (preventing particles to sinter or the deposition of coke), synergistic effects (both metals interact forming intermediates and transitions states) or bi-functional effects (*i.e.* both metal species contribute with different catalytic functions).⁵⁷ The beneficial effect of the bimetallic catalysts is often related to the formation of an alloy.⁶¹ The properties of such an alloy are distinct from those of the individual metals.⁶² Ni particles alloyed with Pt for example are smaller and stronger bound to the support.^{59, 63} Also the higher activity of Ni-Pt-catalysts for hydrogenation of propanal is related to lower binding energy of propanal on the Ni-Pt-Ni(111) subsurface as it is characterized by TPD and DFT calculations.⁶⁴ In a very recent contribution, Ni catalysts were promoted with Cu, Au, Ag, Ru, Rh, Pd, Ir, Fe, Co, Ni, and Sn in order to investigate the hydrogenolysis of lignin. Here, especially Au improves the activity due to smaller Ni-particle size and higher dispersion.⁶⁵ Nevertheless, it is costly to use noble metals like Au, Pd, and Pt to form the bimetallic species.

Besides the emerging popularity of research on bimetallic catalysts and the advances made, there is still a lack of knowledge on the mechanism responsible for these improvements, and more studies are required to establish correlations between results and catalyst modifications at the molecular level⁵⁷.

1.5 Scope of the thesis

The aim of this thesis is to further understand and develop active catalysts for the hydrodeoxygenation of stearic acid working at mild conditions based on Ni/ZrO₂. Therefore, supported metal catalysts were independently investigated by the impact of the support on the one hand side and the effect of the active metal species on the other hand side. The influence of the support on activity and selectivity will be pointed out. It was investigated in two aspects: First, the impact of the crystal phase of ZrO₂ was examined, that synergistically enhances the catalyst activity and providing a higher concentration of oxygen vacancies. Therefore, pure phases of *monoclinic* and *tetragonal* ZrO₂ were synthesized and examined *inter alia* by means of EDX-TEM, XAS and isotopic exchange experiments. Second, ZrO₂ was modified with a hydrothermal synthesis or an impregnation with SiO₂, introducing a novel morphology, increasing the specific surface area and changing the acid-base-properties by the introduction of Brønsted acid sites, shown by high resolution SEM and IR of adsorbed pyridine. This further increases the activity and shifts the selectivity. Moreover, the effect of the metal site was examined. Ni was mixed with Cu that is also an economic metal and reported to be highly active in hydrogenation of carboxylic acid. Physical mixtures with close proximity of Ni and Cu are compared with a Ni_xCu_{1-x}-alloy obtained by co-impregnation. This promotes the hydrodeoxygenation of stearic acid by faster conversion of the substrate and a more rapid formation of long chain alkane in the diesel range (*n*-heptadecane).

Chapter 2

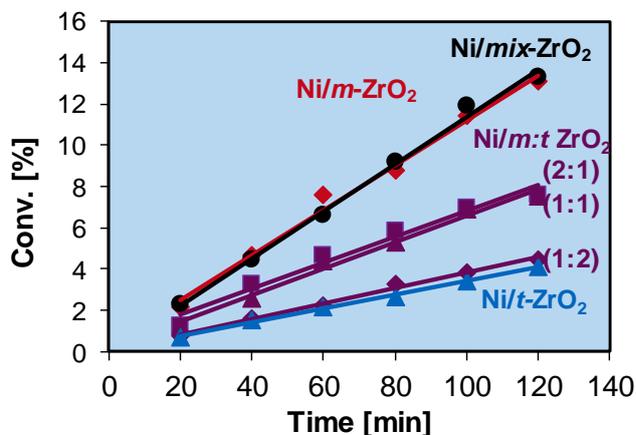

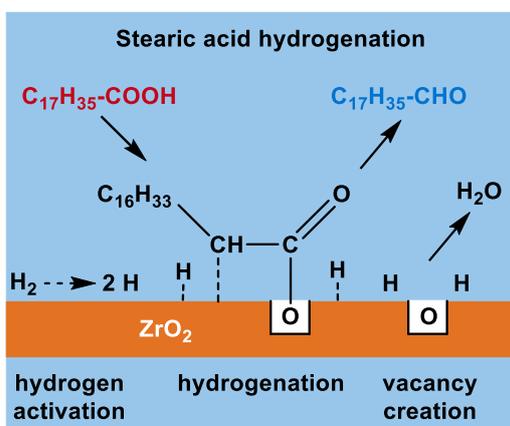

Impact of the Oxygen Defects and the Hydrogen Concentration on the Surface of *Tetragonal* and *Monoclinic* ZrO₂ on the Reduction Rates of Stearic Acid on Ni/ZrO₂

This chapter is based on the following publication:

Foraita, S.; Fulton, J. L.; Chase, Z. A.; Vjunov, A.; Xu, P.; Baráth, E.; Camaioni, D. M.; Zhao, C.; Lercher, J. A., "Impact of the Oxygen Defects and the Hydrogen Concentration on the Surface of Tetragonal and Monoclinic ZrO₂ on the Reduction Rates of Stearic Acid on Ni/ZrO₂." *Chem. - Eur. J.* **2015**, *21*, 2423-2434.

Three different Ni/ZrO₂ catalysts have been tested with regard to their efficiency in the hydrogenation reaction of stearic acid. The Ni/*m*-ZrO₂ catalyst was found to be the best one. A higher concentration of active oxygen defects present in this combination was identified to be responsible for the superiority of this catalyst over the other systems.

Keywords: Microalgae oil • Hydrodeoxygenation • Decarbonylation • EDX-TEM • XAFS • *in situ* IR Spectroscopy • Ni/ZrO₂ • Temperature Programmed Isotope (¹⁸O₂-¹⁶O₂) Exchange

2.1 Abstract

The role of the specific physicochemical properties of ZrO₂ phases on Ni/ZrO₂ has been explored with respect to stearic acid reduction. Conversion on pure *m*-ZrO₂ is 1.3 times more active than on *t*-ZrO₂, while Ni/*m*-ZrO₂ is three times more active than Ni/*t*-ZrO₂. While the hydrodeoxygenation of stearic acid can be catalyzed solely by Ni, the synergistic interaction between Ni and the ZrO₂ support causes the variations in rates. Adsorption of the carboxylic acid group on an oxygen vacancy of ZrO₂ and the abstraction of the α -H with the elimination of the O atom to produce ketene is the key to enhance the overall rate. The hydrogenated intermediate 1-octadecanol is in turn decarbonylated to *n*-heptadecane with identical rates on all catalysts. Decarbonylation of 1-octadecanol is concluded to be limited by the competitive adsorption of reactants and intermediate. The substantially higher adsorption of propionic acid demonstrated by IR spectroscopy and the higher reactivity to O₂ exchange reactions with the more active catalyst indicate that the higher concentration of active oxygen defects on *m*-ZrO₂ compared to *t*-ZrO₂ causes the higher activity of Ni/*m*-ZrO₂.

2.2 Introduction

Microalgae are seen as ideal basis for third-generation biofuels, because of their high growth rates and oil contents as well as the independence of fresh water and arable lands.¹ Their high content of triglycerides makes them a promising resource for liquid transportation fuels. The traditional hydrotreating using sulfided NiMo/Al₂O₃ catalysts has been commercially realized, *i.e.*, the NExBTL process (Neste Oil, Porvoo, 340 kt·a⁻¹).² Although the process for hydrotreating of triglycerides can use the existing infrastructure and requires moderate capital investment, the sulfide catalysts are not ideal for the conversion of a nearly sulfur-free triglycerides feedstock, because they deactivate *via* sulfur elimination and contaminate the product stream with organic sulfides.³

As sulfur-free supported metal catalysts would be attractive alternatives, two types of novel Ni based catalysts to directly convert crude microalgae oil quantitatively to diesel-range hydrocarbons at mild conditions of 260 °C and 40 bar H₂ were developed.⁴ The catalysts used are stable, economic, and scalable. The conversion of the representative model compound stearic acid on Ni/ZrO₂ in presence of H₂ shows that it undergoes reduction of fatty acid solely by Ni and synergistically by Ni and the ZrO₂ support. In the presence of Ni,

the acid is hydrogenated to the aldehyde, followed by decarbonylation of the aldehyde to an alkane. The oxygen vacancies of the ZrO₂ support facilitate the concerted adsorption of fatty acid and the activation of H₂. The α -H abstraction and elimination of H₂O leads to ketene that is formed as a relatively stable intermediate, which has been directly monitored by *in situ* IR spectroscopy.⁵ In the following step, the ketene is hydrogenated to the corresponding aldehyde, which is in turn hydrodeoxygenated to the corresponding alkane *via* decarbonylation. The redundancy of the two catalytic sites increases the overall rate.

The best results are obtained by combining an appropriate concentration of the oxygen defect sites with the metal providing the required dissociated hydrogen. It should be noted in passing that much higher rates of the hydrogenation of CO to methanol were observed for Cu/*m*-ZrO₂ than for Cu/*t*-ZrO₂,⁶ the higher apparent first order rate constant for Cu/*m*-ZrO₂ than for Cu/*t*-ZrO₂ being attributed to the higher concentration of H on the surface of *m*-ZrO₂. The difference in the properties of the lattice oxygen of the two ZrO₂ phases was speculated to be related to the specific adsorption properties for H and CO. As the properties of oxygen vacancies of supports are critical elements for the hydrodeoxygenation of fatty acids, the effect of *m*-, *t*-, and *mix*- phases of ZrO₂ on the hydrodeoxygenation of stearic acid and 1-octadecanol was explored in the liquid phase. The relation between the physicochemical properties of the support, as well as its influence on the properties of the supported Ni particles for catalytic activity and selectivity are explored in the quest to find more active and selective catalysts for fuel synthesis from biomass.

2.3 Results and Discussion

2.3.1 Catalyst characterization

The two phases of *m*- and *t*-ZrO₂ were synthesized by the solvothermal method using water and methanol as solvents, respectively. The XRD patterns for the three ZrO₂ supports are displayed in the appendix of this chapter (page 49). The diffractogram of *monoclinic* ZrO₂ showed the typical characteristic 2θ reflections at 24.5, 28.3, 31.6, and 34.5° (JCPDS card No. 37-1484). The crystal phase of pure *t*-ZrO₂ was confirmed by XRD diffraction peaks at 2θ of 30.4 and 35.1° (JCPDS card No. 17-0923), without peaks from *m*-ZrO₂. Mixed-phase ZrO₂ from calcination of Zr(OH)₄ showed both, characteristic reflections from

m- and *t*-ZrO₂, and the specific sample consisted of 83% *monoclinic* and 17% *tetragonal* phase as derived from **Equation 2-6** (Experimental Section – Materials and Methods, page 44).

The N₂ sorption showed that the specific BET surface areas of three ZrO₂ supports varied between 117 and 160 m²·g⁻¹ (**Table 2-1**). After Ni incorporation and further thermal treatment by calcination and reduction, the specific BET surface areas decreased to approximately 70 m²·g⁻¹ for the three Ni/ZrO₂ catalysts (**Table 2-2**). The concentration of acid and base sites of the parent ZrO₂ and Ni/ZrO₂ were determined from the temperature-programmed desorption (TPD) of NH₃ and CO₂, respectively. The concentrations of Lewis acid and base sites of three ZrO₂ supports were almost identical at 0.30 and 0.04 mmol·g⁻¹, respectively. Normalized to the specific surface areas, Lewis acidity and basicity of the supports were 2.0 and 0.3 μmol·m⁻², which demonstrates that the acid and base properties are very similar. With Ni deposited, the acid site concentrations of the three Ni/ZrO₂ samples decreased by 50% to 0.11-0.14 mmol·g⁻¹, while the concentrations of base sites were almost unchanged (0.04 mmol·g⁻¹). This suggests that deposited Ni (metal, oxide or hydroxide) particles interact with and block Lewis acid sites. The surface areas as well as the concentration and strength of acid and base sites for three ZrO₂ and Ni/ZrO₂ samples are shown to be very similar; therefore, the influence from these factors is expected to be minimal.

Table 2-1. Physicochemical properties of ZrO₂ supports.

Support	S _{BET}	Concentration of acid sites ^a		Concentration of basic sites ^b	
	[m ² ·g ⁻¹]	[mmol·g ⁻¹]	[μmol·m ⁻²]	[mmol·g ⁻¹]	[μmol·m ⁻²]
<i>mix</i> -ZrO ₂	162	0.33	2.0	0.06	0.37
<i>m</i> -ZrO ₂	117	0.30	2.5	0.04	0.36
<i>t</i> -ZrO ₂	149	0.30	1.9	0.04	0.27

[a] Determined by TPD of NH₃. [b] Determined by TPD of CO₂.

A) EDX-TEM images

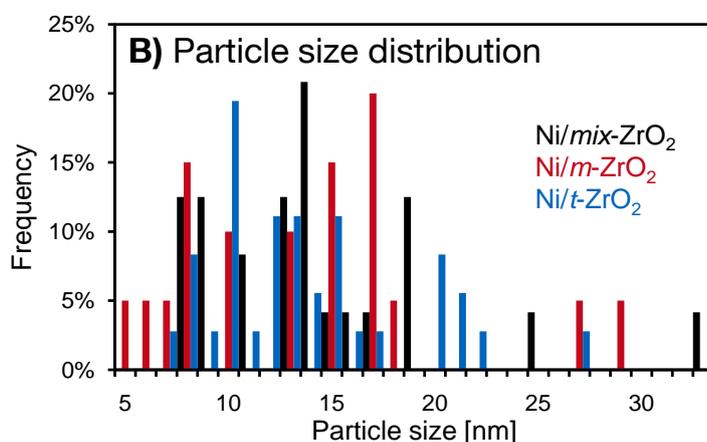

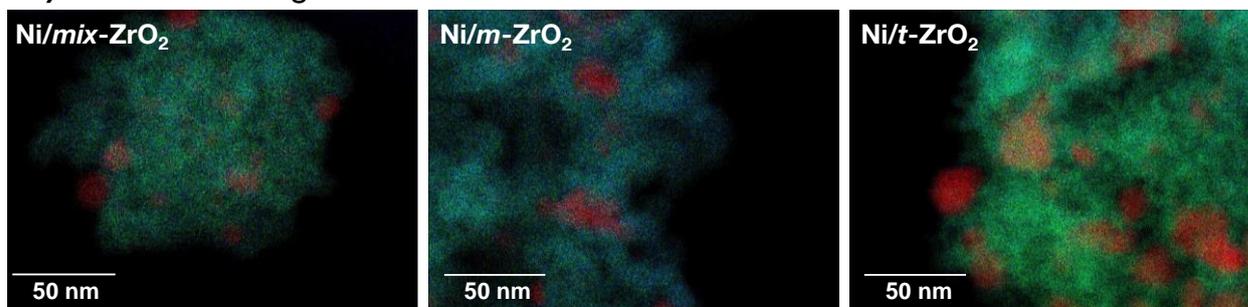

Figure 2-1. A) TEM images with Energy-dispersive X-ray spectroscopy (EDX) mapping (Ni in red, Zr in green, O in blue) and B) corresponding Ni particle size distribution of three Ni/ZrO₂ catalysts.

The characteristic diffraction peaks for *m*- and *t*-ZrO₂ for the three Ni/ZrO₂ (Figure A 2-1, B, Appendix) samples were in good agreement with the diffractogram of parent supports (Figure A 2-1, A), suggesting that the synthesized phases are very stable

against phase transformation during impregnation, calcination, and reduction. The distinctive peaks at 2θ of 44.6° and 51.9° are assigned to Ni(111) and Ni(200), respectively. Based on the Scherrer equation, the average particle diameter, $d_{\text{Ni}(111)}$, of Ni/mix-ZrO₂, Ni/m-ZrO₂, and Ni/t-ZrO₂ were 12, 13, and 12 nm, respectively.

Apart from XRD measurement on determining the Ni-particle size, TEM images with Energy-dispersive X-ray spectroscopy (EDX) mapping of Ni on ZrO₂ (**Figure 2-1, A**) and the corresponding particle size distributions (**Figure 2-1, B**) are also shown. Note that the TEM images of ZrO₂ supported Ni particles are difficult to interpret because of the low metal/support contrast.⁷ Therefore, element sensitive EDX-technique was applied to differentiate between metal species and the support. It shows Ni particles in contact with ZrO₂. From TEM micrographs spherically shaped Ni particles with a heterogeneous size distribution, typically for wetness impregnation technique, and an average diameter of 14-15 nm were detected, *i.e.*, larger in size than the average size determined from XRD. This is attributed to the fact that TEM counts the size of visible Ni⁰ particles, while XRD accounts also for particles with too low contrast to be determined by TEM measures.⁸ Generally, Ni particles show comparable sizes and distributions and shapes on three ZrO₂ supports determined from both XRD patterns and TEM images.

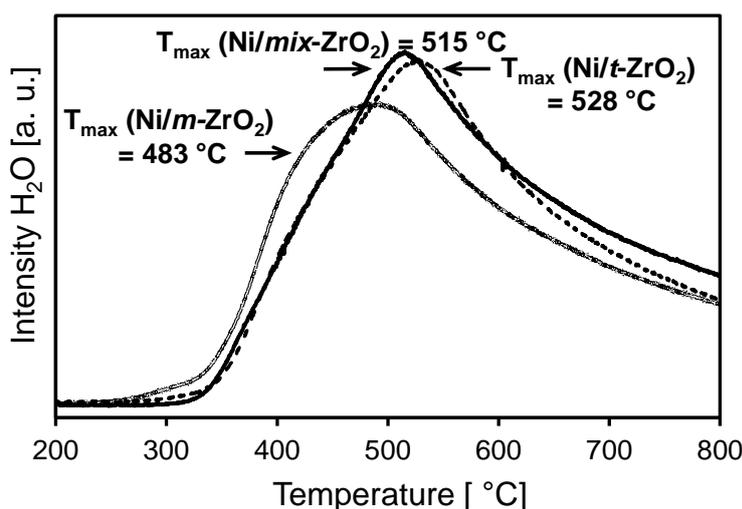

Figure 2-2. Temperature programmed reduction with H₂ on Ni/mix-ZrO₂, Ni/m-ZrO₂, and Ni/t-ZrO₂.

The state of Ni on ZrO₂ was probed by TPR of three calcined Ni/ZrO₂ catalysts using H₂ (**Figure 2-2**). TPR showed that the maximum rates of reduction (monitored by H₂O formation) appeared between 483 °C and 528 °C. The maximum reduction rate for Ni/*m*-ZrO₂ occurred at 483 °C, whereas for Ni/*mix*-ZrO₂ and Ni/*t*-ZrO₂, the reduction rates peaked at somewhat higher temperatures, 515 and 528 °C, respectively. Bulk NiO is usually reduced at 400 °C,⁹ and the higher temperature observed here is tentatively attributed to the reduction of small nickel oxide crystallites interacting strongly with ZrO₂.⁸ Reducing the three calcined Ni/ZrO₂ catalysts at 500, 550, 600 °C showed that the Ni particles gradually grew as a function of the reduction temperature, leading to particles with 13, 14, and 19 nm diameter, respectively (determined by Scherrer Equation from XRD patterns, **Table A 2-1**). The catalytic activities for stearic acid hydrogenation decreased in the order of 2.6, 2.0, and 1.0 mmol·g⁻¹·h⁻¹, indicating that the specific rates of hydrogenation decreased in accordance with the increasing size of the Ni particles. To achieve a high hydrodeoxygenation rate, the calcined Ni/ZrO₂ sample were reduced at 500 °C for all samples discussed here.

2.3.2 States of Ni and the ZrO₂ polymorphic phases by XAFS

The states of Ni and Zr in the three different Ni/ZrO₂ catalysts are analyzed by Ni- and Zr-K edge XAFS. The Ni K-edge XANES spectra demonstrate that Ni/*m*-ZrO₂, Ni/*t*-ZrO₂, and Ni/*mix*-ZrO₂ catalysts contained a higher concentration of Ni⁰ than Ni^{II} (**Figure 2-3, A**). The Fourier transformed Ni K-edge EXAFS spectra were quite similar for the three Ni/ZrO₂ catalysts, which is in good agreement with the other results discussed. The fractions of Ni⁰ and Ni^{II}, analyzed by a linear combination from XANES, are compiled in **Table A 2-2**. The three Ni/ZrO₂ catalysts contained approximately 70-79% metallic Ni⁰ and 21-30% Ni^{II} before reaction. The Ni-Ni distances and coordination numbers (**Figure 2-3, B**) are identical to that of bulk Ni. After reaction in presence of H₂, the fraction of metallic Ni⁰ increased to 84-86%. Fitting the EXAFS using a theoretical standard (**Figure A 2-2**) showed that also for these experiments the coordination number of the first Ni-Ni shell was identical to that for a bulk metal. This is consistent with Ni nanoparticle diameters that are greater than about 5 nm as shown also by TEM (**Figure 2-1, B**). No indication of Ni-Zr scattering, that would be present as a result of a separate, atomically dispersed Ni phase, was observed. The Ni EXAFS structure for Ni/*m*-ZrO₂ and for Ni/*t*-ZrO₂ were nearly identical up to

$R = 8 \text{ \AA}$ and hence the observed higher reactivity of Ni/*m*-ZrO₂ (described below) does not appear to be related to differences in the Ni nanostructures.

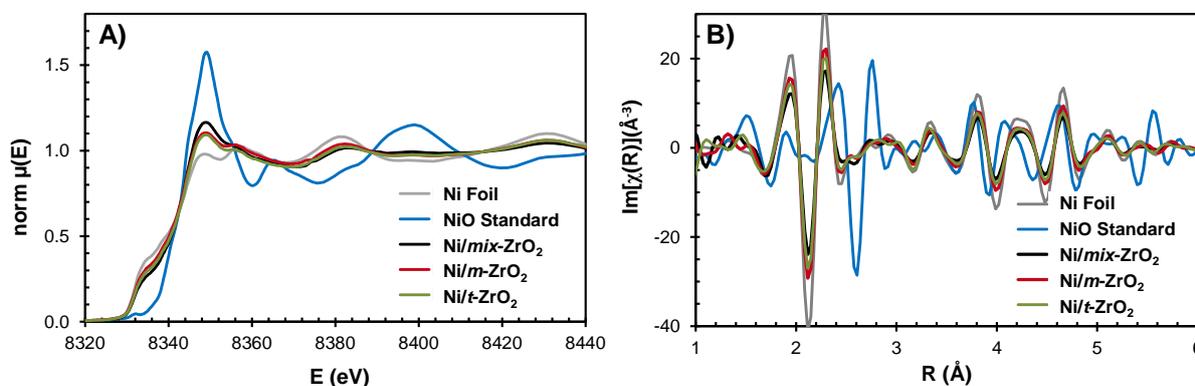

Figure 2-3. **A)** Ni *K*-edge XANES spectra, and **B)** Ni *K*-edge EXAFS Fourier transforms (FTs) $\text{Im}[\chi(R)](\text{\AA}^{-3})$ spectra of Ni-standards (Ni⁰ foil, NiO) and Ni/ZrO₂ catalysts (Ni/*mix*-ZrO₂, Ni/*m*-ZrO₂, Ni/*t*-ZrO₂) at ambient temperature.

The XAS of the Zr *K*-edge of the three ZrO₂ (**Figure 2-4, A**) shows that the XANES of *mix*-ZrO₂, *m*-ZrO₂, and *t*-ZrO₂ indicate profound differences for *t*-ZrO₂ in comparison to *m*-ZrO₂ including the stronger $1s \rightarrow 4d$ shoulder at 18000 eV, the apparent white line doublet at 18020 eV and the scattering peak at 18045 eV. A more subtle feature is the shoulder on the leading edge of the white line at 18015 eV, which appeared also for the pure *t*-ZrO₂. All features are consistent with published values of ZrO₂.¹⁰ Using the XANES to differentiate *t*-ZrO₂ and *m*-ZrO₂, a linear combination fit to the *mix*-ZrO₂ yields a ratio of 25% *t*-ZrO₂ and 75% *m*-ZrO₂ (**Table A 2-3**), which is in good agreement with the XRD results in **Figure A 2-1**. After deposition of Ni, the structure of ZrO₂ was hardly changed (**Figure A 2-3**). Calcination and reduction steps, however, alter the ZrO₂ phase distribution of *t*-ZrO₂ and *mix*-ZrO₂. In both instances, *t*-ZrO₂ is partially converted to *m*-ZrO₂ phase. The *t*-ZrO₂ is converted to about 38% *m*-ZrO₂ while *mix*-ZrO₂ is converted to about 94% *m*-ZrO₂.

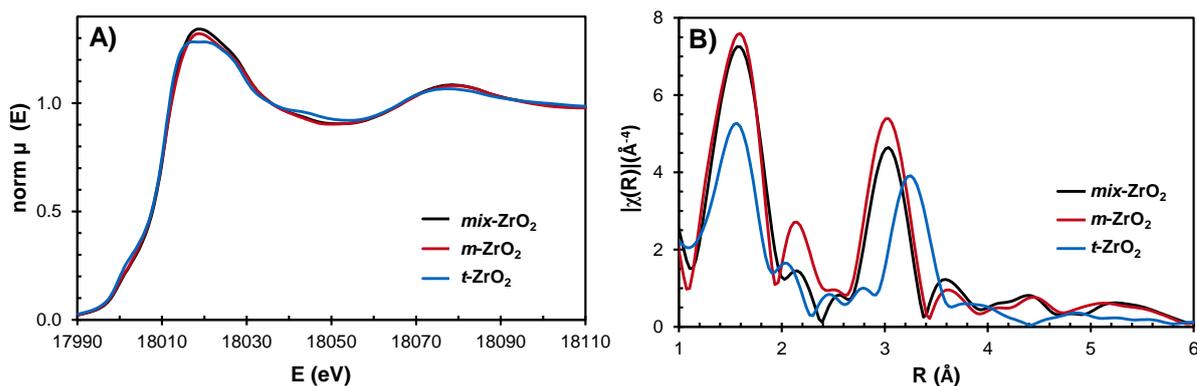

Figure 2-4. A) Zr *K*-edge XANES spectra and B) Zr *K*-edge EXAFS spectra Fourier transforms (FTs) $\text{Im}[\chi(R)](\text{\AA}^{-4})$ spectra of *mix*-ZrO₂, *m*-ZrO₂, and *t*-ZrO₂ at ambient temperature.

In line with the XRD patterns, the Fourier transformed Zr EXAFS (**Figure 2-4, B**) showed high similarity between *mix*-ZrO₂ and *m*-ZrO₂. The first maximum at 1.5 Å is assigned to the nearest shell (O), while the second peak at 3.0-3.3 Å is attributed to the next nearest shell (Zr) around the Zr central atom.¹¹ The shift of the peak at 3.3 Å for *t*-ZrO₂ (compared to 3.0 Å for *m*-ZrO₂) in the FT imaginary $\chi(R)$ plot (**Figure 2-4, B**) is attributed to the fact that the Zr-O bond distance is different in *m*-ZrO₂ (Zr-O_I, trigonal and Zr-O_{II}, tetrahedral) and *t*-ZrO₂ (Zr-O_{II}, tetrahedral).¹² This peak shift from 3.3 to 3.0 Å is also related to a decreasing symmetry as varying from *tetragonal* to *monoclinic* phase.^{11a}

2.3.3 Hydrogenation of stearic acid over ZrO₂

To investigate the effect of ZrO₂ morphologies, stearic acid was converted first on the bare supports. The three supports led to similar distributions of product after 6 h (**Figure 2-5, B**). The major products were the aldehyde (selectivity: 60-75%) and diheptadecyl ketone (selectivity: 18-27%), as well as small concentrations of *n*-heptadecane (selectivity: 6-13%).

The reduction and ketonization of the carboxylic acid has been reported to be catalyzed by modestly redox active oxides such as ZrO₂, CeO₂, Cr₂O₃, Fe₂O₃, ZnO, and TiO₂ at 300-400 °C.¹³ The catalyzed reaction involves the adsorption of the acid on oxygen defect sites of the metal oxides to form a carboxylate. The carboxylates are assumed to be adsorbed parallel to the oxide surface because of the strong interaction of the α -H with the surface. Ketene and H₂O are formed through abstraction by one of the α -H. Subsequently, a nearby

carboxylate reacts with the activated H (**Scheme 2-1, A**) atoms to form the aldehyde or with adsorbed ketene to form the ketone by eliminating CO₂ (**Scheme 2-1, B**).

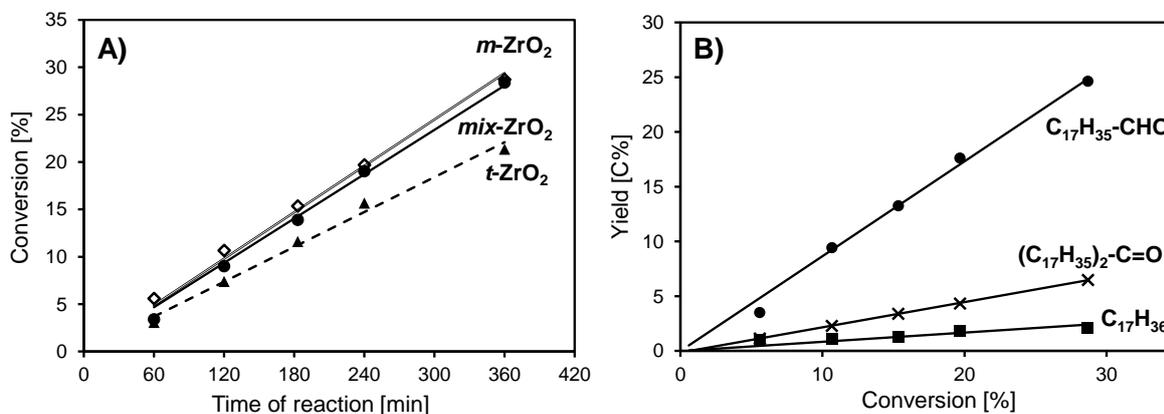

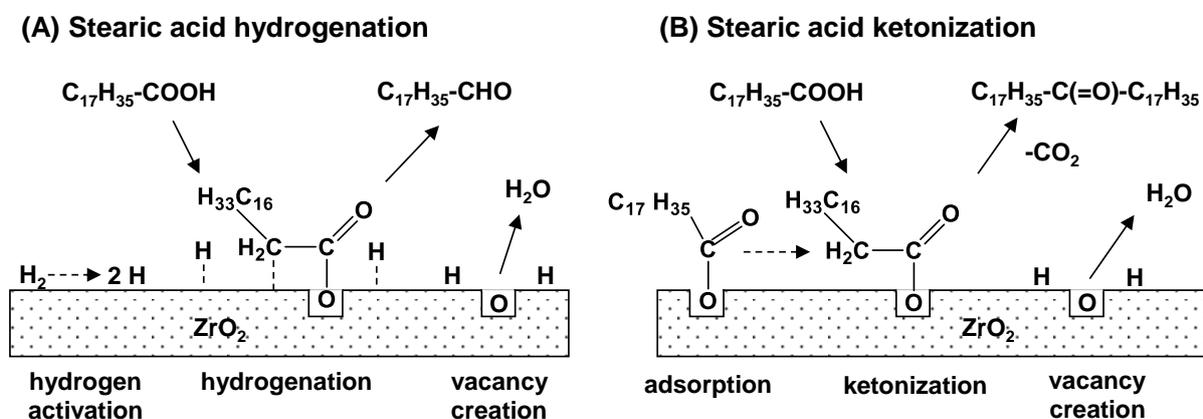

Figure 2-5. A) Conversion of stearic acid over *m*-ZrO₂, *mix*-ZrO₂ and *t*-ZrO₂ as a function of time. B) Yields of octadecanal, diheptadecyl ketone, and *n*-heptadecane over *m*-ZrO₂ as a function of stearic acid conversion. Reaction conditions: stearic acid (0.5 g), ZrO₂ (0.5 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm. Reproducibility of the rates has been better than ± 5%.

Scheme 2-1. Mechanisms for (A) hydrogenation and (B) ketonization of stearic acid on the surface of ZrO₂.

The rates of stearic acid conversion on *mix*- and *m*-ZrO₂ were similar at 28% and 29% after 6 h corresponding to rates of 0.017 and 0.016 mmol·g⁻¹·h⁻¹, respectively. The rate on *t*-ZrO₂ was 20% lower (**Table 2-3**). The *mix*-ZrO₂ consisted of a majority of 83% *m*-ZrO₂ evidenced by the XRD patterns. This demonstrates that the *monoclinic* phase of ZrO₂ is more active for stearic acid reduction even in the absence of metal sites.

Table 2-3. Comparison of stearic acid conversion over ZrO₂ supports.^a

Catalyst	Rate [mmol·g ⁻¹ ·h ⁻¹]	Conv. [%]	Selectivity [C%]		
			C ₁₇	C ₁₇ -CHO	(C ₁₇ H ₃₅) ₂ C=O
<i>mix</i> -ZrO ₂	0.017	28	13	60	27
<i>m</i> -ZrO ₂	0.016	29	6.9	75	18
<i>t</i> -ZrO ₂	0.013	21	6.0	72	22

[a] Reaction conditions: stearic acid (0.5 g), ZrO₂ (0.5 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, 6 h, stirring at 600 rpm. Reproducibility of the rates has been better than $\pm 5\%$.

2.3.4 Hydrogenation of stearic acid with Ni/ZrO₂

The results of the conversion of stearic acid on Ni supported on *m*-, *t*-, and *mix*-ZrO₂ are shown in **Figure A 2-4, A**. The primary initial product was the hydrogenated alcohol with a selectivity of 86-94%, and further decarbonylated C₁₇ and hydrodeoxygenated C₁₈ hydrocarbons were obtained in minor quantities (total selectivity: 5-10%) (**Figure A 2-4, B**). With Ni/ZrO₂ ketonization was eliminated. In addition, the hydrogenation rate on Ni/*m*-ZrO₂ (2.6 mmol·g⁻¹·h⁻¹) was two orders of magnitude higher than that on *m*-ZrO₂ (0.017 mmol·g⁻¹·h⁻¹). This is attributed to the fact that Ni aided the dissociation of H₂, dramatically enhancing the rate of formation and consequently increasing the number of oxygen vacancies on the ZrO₂ support, thereby substantially increasing the rate of ketene formation by the support. Additionally, in presence of H₂, the direct Ni catalyzed hydrogenation of stearic acid dominates the overall catalytic chemistry. The facile availability of H essentially eliminates the much slower ketonization route.

Comparison of the three different Ni/ZrO₂ catalysts shows that the rate of conversion of stearic acid over Ni/*m*-ZrO₂ (2.6 mmol·g⁻¹·h⁻¹) was almost three times higher than that over Ni/*t*-ZrO₂ (0.9 mmol·g⁻¹·h⁻¹) (**Table 2-4**). The catalytic activities of Ni/*mix*-ZrO₂ and Ni/*m*-ZrO₂ for producing 1-octadecanol were quite similar with rates of 2.5 and 2.6 mmol·g⁻¹·h⁻¹, respectively. To further verify such a phase effect, Ni supported on physical mixtures of *m*-ZrO₂ and *t*-ZrO₂ (**Figure A 2-4, A**) were used to reduce stearic acid under otherwise identical conditions. The hydrogenation rates followed the sequence of 1.7, 1.5, and 1.0 mmol·g⁻¹·h⁻¹ for the 1:2, 1:1, and 2:1 ratios of and Ni/*m*:*t*-ZrO₂ samples (**Table 2-4**).

The rates with the physically mixed supports were expectedly between the rates of pure Ni/*m*-ZrO₂ (2.6 mmol·g⁻¹·h⁻¹) and Ni/*t*-ZrO₂ samples (0.9 mmol·g⁻¹·h⁻¹). These results show that the rate of reduction is directly correlated with the concentration of *m*-ZrO₂ (Figure 2-6).

Table 2-4. Comparison of stearic acid conversion over different Ni/ZrO₂ catalysts.^a

Catalyst	Rate [mmol·g ⁻¹ ·h ⁻¹]	Conv. [%]	Selectivity [C%]		
			C ₁₇	C ₁₈	C ₁₈ -OH
Ni/ <i>mix</i> -ZrO ₂	2.5	13.3	5.5	0.4	94
Ni/ <i>m</i> -ZrO ₂	2.6	12.7	6.3	0.5	93
Ni/2:1 <i>m</i> : <i>t</i> -ZrO ₂	1.7	7.1	11	2.0	87
Ni/1:1 <i>m</i> : <i>t</i> -ZrO ₂	1.5	7.3	9.4	1.6	89
Ni/1:2 <i>m</i> : <i>t</i> -ZrO ₂	1.0	4.4	12	2.0	86
Ni/ <i>t</i> -ZrO ₂	0.9	4.1	7.8	0.2	92

[a] Reaction conditions: stearic acid (1.0 g), Ni/ZrO₂ (10 wt%, 0.10 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, 2 h, stirring at 600 rpm. Reproducibility of the rates has been better than ± 5%.

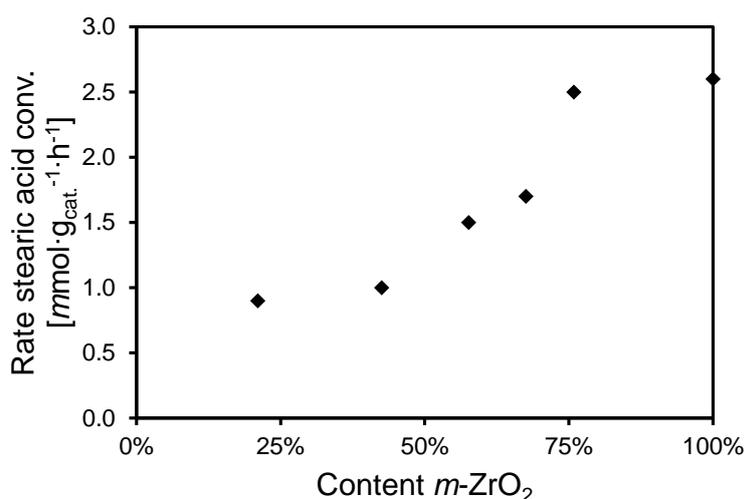

Figure 2-6. Rates for the conversion of stearic acid depending on the content of *monoclinic* ZrO₂ in a Ni/ZrO₂ catalyst. Reaction conditions: stearic acid (1.0 g), Ni/ZrO₂ (10 wt%, 0.1 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm.

2.3.5 Decarbonylation of 1-octadecanol over Ni/ZrO₂

The hydrodeoxygenation of stearic acid on Ni/ZrO₂ proceeded with hydrogenation to 1-octadecanol as the apparent primary product (**Figure A 2-4, B**). To better understand the kinetic sequence, 1-octadecanol conversion was studied in separate experiments (**Figure 2-7**). Selectivities of 95% *n*-heptadecane (C₁₇) and 5% *n*-octadecane (C₁₈) were observed at 36% conversion after 2 h for all samples. This shows that direct decarbonylation (-CO) of the aldehyde, formed *via* the dehydrogenation of the alcohol took place. The minor concentration of *n*-octadecane is concluded to be catalyzed by the sequential dehydration-hydrogenation of the alcohol on acid sites of Ni/ZrO₂. The rate of decarbonylation of 1-octadecanol (6.3 mmol·g⁻¹·h⁻¹) was identical on all Ni/ZrO₂ catalysts (**Figure 2-7** and **Table 2-5**), and such rate was 3-7 times higher than that of stearic acid hydrogenation (2.6 and 0.9 mmol·g⁻¹·h⁻¹) on Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ catalysts. This suggests that the rate-determining step is related to the reductive deoxygenation of the fatty acid. The result also implies that the decarbonylation of 1-octadecanol is not sensitive with respect to the ZrO₂ phases, and that the active sites of Ni particles convert 1-octadecanol with identical rates.

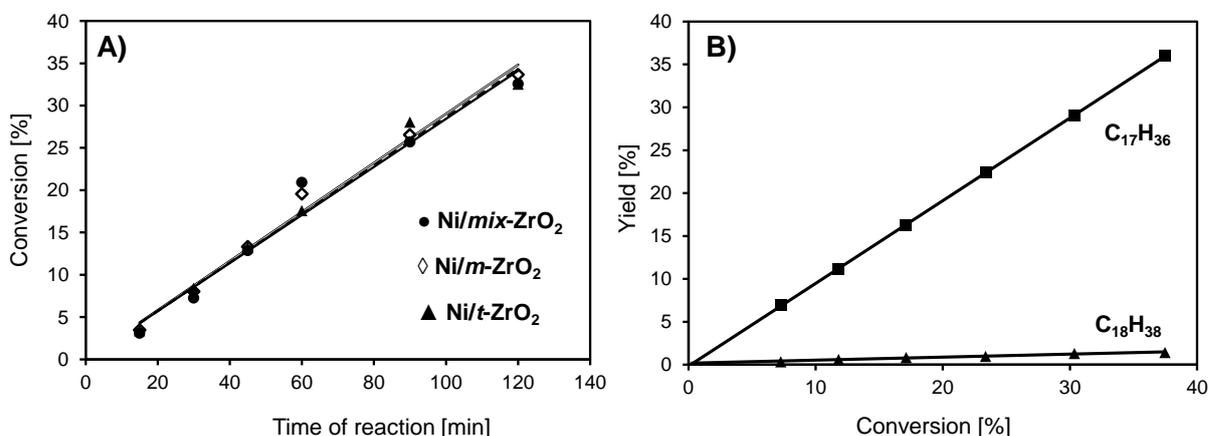

Figure 2-7. A) Conversion of 1-octadecanol as a function of time. B) Yield of *n*-heptadecane and *n*-octadecane over Ni/*m*-ZrO₂ as a function of 1-octadecanol conversion. Reaction conditions: 1-octadecanol (1.0 g), Ni/ZrO₂ (10 wt%, 0.10 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm. Reproducibility of the rates has been better than $\pm 5\%$.

Table 2-5. Comparison of 1-octadecanol conversion over three Ni/ZrO₂ catalysts.^a

Catalyst	Rate [mmol·g ⁻¹ ·h ⁻¹]	Conv. [%]	Selectivity [C%]	
			C ₁₇	C ₁₈
Ni/mix-ZrO ₂	6.3	33	95	5.0
Ni/m-ZrO ₂	6.3	33	96	4.0
Ni/t-ZrO ₂	6.2	32	97	3.0

[a] Reaction conditions: 1-octadecanol (1.0 g), Ni/ZrO₂ (10 wt%, 0.10 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, 2 h, stirring at 600 rpm. Reproducibility of the rates has been better than $\pm 5\%$.

2.3.6 Overall hydrodeoxygenation of stearic acid to *n*-heptadecane over Ni/ZrO₂

The kinetics of overall hydrodeoxygenation of stearic acid to *n*-heptadecane over Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ at 260 °C is shown in **Figure 2-8**. 1-Octadecanol is the initial product, being formed in yields of 60-80%, although the final product is primarily *n*-heptadecane. Octadecanal and 1-octadecanol being in equilibrium *via* facile Ni-catalyzed hydrogenation/dehydrogenation reactions account for this conversion of 1-octadecanol to *n*-heptadecane. At the high H₂ pressure (40 bar), the concentration of aldehyde is too low to be observed. Nevertheless, the intermediate octadecanal is slowly and irreversibly decarbonylated to *n*-heptadecane, effectively converting 1-octadecanol into *n*-heptadecane. 1-Octadecanol also underwent esterification with stearic acid to form stearyl stearate (reversible reaction) as well as dehydration/hydrogenation to *n*-octadecane as side-products. Ni/*m*-ZrO₂ achieved a much higher rate for reduction of stearic acid forming 1-octadecanol as well as overall hydrodeoxygenation rates for producing *n*-heptadecane from stearic acid (**Figure 2-8**), which is fitted with the results from kinetic measurements of individual steps.

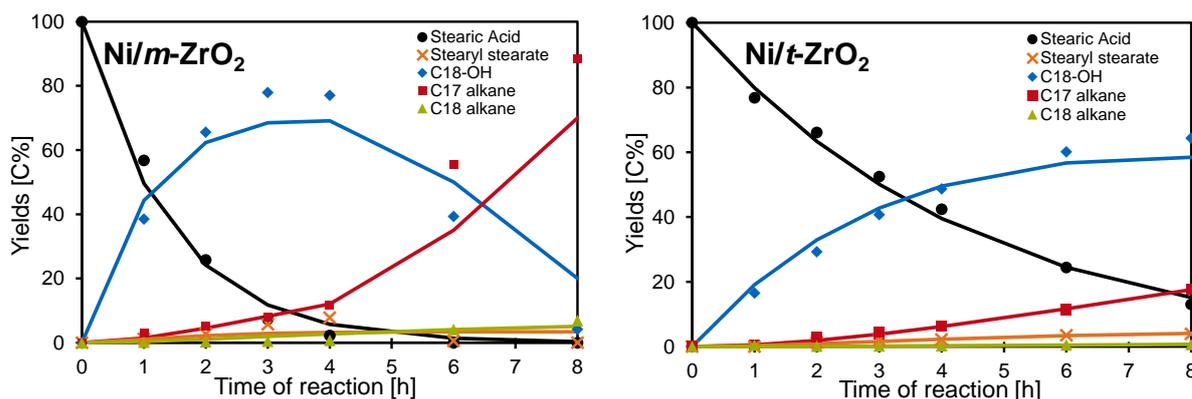

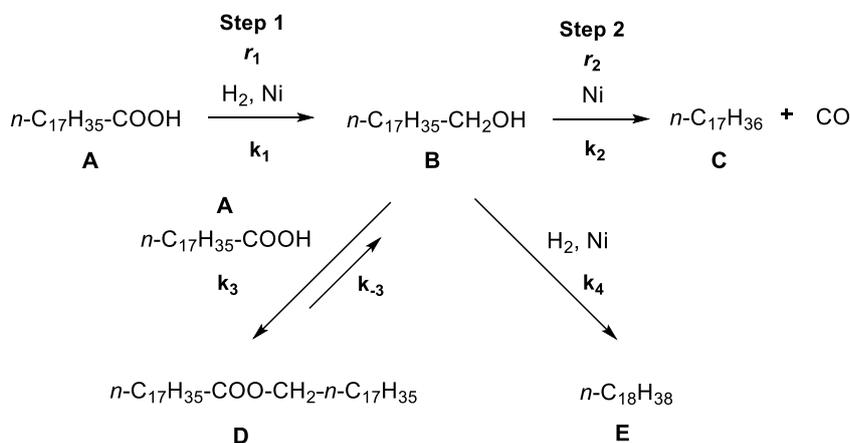

Figure 2-8. Fitting data for hydrodeoxygenation of stearic acid using Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ as a function of time (solid point: experimental data, line: fitted data). Reaction conditions: stearic acid (0.5 g), Ni/ZrO₂ (10 wt%, 0.2 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm.

Scheme 2-2. Proposed elementary steps for hydrodeoxygenation of stearic acid to *n*-heptadecane (C₁₇).

A simplified network for hydrodeoxygenation of stearic acid over Ni/ZrO₂ catalysts is displayed in **Scheme 2-2**. The elementary steps include hydrogenation of stearic acid (A) to 1-octadecanol (B), then 1-octadecanol (B) is decarbonylated to *n*-heptadecane (C). In addition, dehydration/hydrogenation of 1-octadecanol (B) forms *n*-octadecane without carbon loss, and esterification of stearic acid (A) and 1-octadecanol (B) produces stearyl stearate ester (D). The latter esterification reaction is in equilibrium. The H₂ partial pressure before and after reaction was 40 bar. Assuming first-order reaction steps, the elementary rate equations are listed as follows (**Equation 2-1** to **Equation 2-5**):

Equation 2-1

$$\frac{dc(A)}{dt} = -k_1c(A) - k_3c(A)c(B) + k_{-3}c(D)$$

Equation 2-2

$$\frac{dc(B)}{dt} = k_1c(A) - k_2c(B) - k_3c(B)c(A) + k_{-3}c(D) - k_4c(B)$$

Equation 2-3

$$\frac{dc(C)}{dt} = k_2c(B)$$

Equation 2-4

$$\frac{dc(D)}{dt} = k_3c(A)c(B) - k_{-3}c(D)$$

Equation 2-5

$$\frac{dc(E)}{dt} = k_4c(B)$$

The rate **Equation 2-1** to **Equation 2-5** were numerically integrated and fit by least squares to the kinetic data for hydrodeoxygenation of stearic acid over Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ (**Figure 2-8**). The fitted rate constant ($k_1 = 2.7 \times 10^{-3} \text{ min}^{-1}$) for stearic acid hydrogenation over Ni/*m*-ZrO₂ was almost identical to the value ($k_1 = 2.2 \times 10^{-3} \text{ min}^{-1}$) from individual reaction step measurement (**Table 2-6**). However, the reaction rates for alcohol decarbonylation were not consistent between the fitted data ($k_2 = 2.4 \times 10^{-4} \text{ min}^{-1}$) and calculated individual measurement ($k_2 = 7.5 \times 10^{-3} \text{ min}^{-1}$). The rate constants of the side-reactions k_3 ($k_3 = 5.0 \times 10^{-6} \text{ min}^{-1}$) for esterification as well as k_4 for dehydration/hydrogenation towards *n*-octadecane ($k_4 = 1.2 \times 10^{-5} \text{ min}^{-1}$) were two orders of magnitude lower than k_1 ($k_1 = 2.7 \times 10^{-3} \text{ min}^{-1}$). The substantially lower rate constant k_2 in the fitted overall hydrodeoxygenation is attributed to either competition of stearic acid and 1-octadecanol in the conversion (major part), or to side reactions such as esterification and dehydration of 1-octadecanol (a very minor part). Meanwhile, the apparent esterification rate constant k_3 ($5.0 \times 10^{-6} \text{ min}^{-1}$) was five magnitudes higher than its reverse rate k_{-3} ($1.9 \times 10^{-11} \text{ min}^{-1}$). Therefore, the forward reaction of esterification is concluded to be more favored in the tested time period. Note that as 1-octadecanol and stearic acid are consumed continuously along the reaction time, the equilibrium would be shifted to the reverse reaction for cleavage the C–O bond of stearyl stearate. Compared to Ni/*m*-ZrO₂ ($k_1 = 2.7 \times 10^{-3} \text{ min}^{-1}$), Ni/*t*-ZrO₂ showed

three times lower hydrogenation rate ($k_1 = 9.2 \times 10^{-4} \text{ min}^{-1}$) for hydrogenation of stearic acid (**Table 2-6, B**), which was identical to the rate comparison in the individual steps measurement (**Table 2-6, A**). The rate of 1-octadecanol decarbonylation on Ni/*t*-ZrO₂ ($k_2 = 2.1 \times 10^{-4} \text{ min}^{-1}$) was identical to that on Ni/*m*-ZrO₂ ($k_2 = 2.4 \times 10^{-4} \text{ min}^{-1}$) in the overall hydrodeoxygenation of stearic acid (**Table 2-6, B**), which is in agreement with the rate comparison in the individual measurements ($k_2 = 7.4$ and $7.5 \times 10^{-3} \text{ min}^{-1}$, respectively, **Table 2-6, A**). The lower rate of 1-octadecanol decarbonylation in the overall hydrodeoxygenation process compared to individual steps is majorly attributed to the competition in species adsorption with stearic acid onto the active Ni sites. For the reversible esterification (k_3 and k_{-3}) and dehydration (k_4) of 1-octadecanol, the rates were comparable on Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ catalysts (**Table 2-6, B**) probably because of their similar acidity and basicity. In addition, the rate constants of the side reactions (k_3 , k_{-3} , and k_4) were magnitudes lower than the major reaction steps of stearic acid hydrogenation (k_1) and decarbonylation of 1-octadecanol (k_2), implying the influence of side reactions is minimal compared to the overall hydrodeoxygenation.

Table 2-6. A) Rate constants in the individual steps and **B)** fitted rate constants in the overall hydrodeoxygenation of stearic acid with Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ (normalized to conditions: stearic acid 1.0 g, catalyst 0.1 g, 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm).

A) Rate constants determined from individual steps					
Catalyst	Step 1: Hydrogenation of stearic acid	Step 2: Decarbonylation/ hydrogenation of 1-octadecanol			
	$r_1 = k_1 c(\text{C}_{17}\text{H}_{35}\text{COOH})$	$r_2 = k_2 c(\text{C}_{17}\text{H}_{35}\text{-CH}_2\text{OH})$			
Ni/ <i>m</i> -ZrO ₂	$k_1 = 2.2 \times 10^{-3} \text{ min}^{-1}$	$k_2 = 7.5 \times 10^{-3} \text{ min}^{-1}$			
Ni/ <i>t</i> -ZrO ₂	$k_1 = 7.9 \times 10^{-4} \text{ min}^{-1}$	$k_2 = 7.4 \times 10^{-3} \text{ min}^{-1}$			

B) Fitted rate constants in the overall hydrodeoxygenation of stearic acid					
	k_1 (min ⁻¹)	k_2 (min ⁻¹)	k_3 (min ⁻¹)	k_{-3} (min ⁻¹)	k_4 (min ⁻¹)
Ni/ <i>m</i> -ZrO ₂	2.7×10^{-3}	2.4×10^{-4}	5.0×10^{-6}	1.9×10^{-11}	1.2×10^{-5}
Ni/ <i>t</i> -ZrO ₂	9.2×10^{-4}	2.1×10^{-4}	1.5×10^{-6}	2.9×10^{-11}	8.5×10^{-6}

The mechanism for hydrodeoxygenation of stearic acid proceeds *via* two routes. The first relies on the Ni catalyzed reductive deoxygenation to octadecanal, which is equilibrated with 1-octadecanol. The aldehyde is in turn decarbonylated on Ni. The second pathway starts with the adsorption of stearic acid on the oxygen vacancies of ZrO₂ to form the carboxylate, and then through deoxygenation to aldehyde. The reductive deoxygenation on pure ZrO₂ support is quite low (0.016 mmol·g⁻¹·h⁻¹) presumably because H₂ dissociation – required to maintain oxygen vacancies through desorption of water – is slow (the HD formation, characteristic for H₂ dissociation was at least 10² times faster in presence of Ni than with ZrO₂ alone). The redundant catalytic pathways of Ni and ZrO₂ generate the appropriate combination enhancing the hydrogenation rate of stearic acid by 150 times (2.6 mmol·g⁻¹·h⁻¹) compared to *m*-ZrO₂ (0.016 mmol·g⁻¹·h⁻¹). The rate on Ni/ZrO₂ is much higher than that on other Ni based catalysts such as Ni/C, Ni/Al₂O₃, and Ni/SiO₂,⁵ suggesting a strong support effect. In summary, it can be concluded that the major active sites are the Ni particles. The Ni particles on *m*- and *t*-ZrO₂ supports have been shown to be almost identical by TEM, XRD, TPR, EXAFS, and XANES, as well as by the rates of decarbonylation of 1-octadecanol. It should be emphasized at this point that the BET surface areas, the concentrations of acid and base sites on parent *m*- and *t*-ZrO₂ and Ni/ZrO₂ were nearly identical. Therefore, the rate differences of stearic acid hydrodeoxygenation on Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ are concluded to be related to differences in the adsorption and/or redox properties. These properties will be explored by spectroscopically characterizing variations in the sorption mode and strength of propionic acid as well as with the temperature programmed isotopic exchange (¹⁸O-¹⁶O) of *m*- and *t*-phases of ZrO₂.

2.3.7 Comparison of in situ IR spectroscopy of adsorbed propionic acid on *m*- and *t*-ZrO₂ in the gas phase

The IR spectra of free propionic acid in the gas phase and adsorbed propionic acid on *m*-ZrO₂ are shown in **Figure 2-9**. The absorbance bands at 3600-3700 cm⁻¹ for propionic acid in the gas phase (**Table A 2-4**) are ascribed to the O–H stretching vibration of the carboxylic acid group. The C=O vibration of the carboxylic acid group is assigned to the doublet at 1700 and 1800 cm⁻¹ and the C–O vibration to the band at 1150 cm⁻¹. The C–H stretching vibrations of –CH₃ and –CH₂ are assigned to the bands at 2945 and 2986 cm⁻¹. The in-plane bending vibration of C–H are assigned to the triplet bands between 1400-

1500 cm⁻¹ and at 1080 cm⁻¹. When the carboxylic group of the propionic acid was adsorbed on the ZrO₂ surface, the $\nu(\text{O-H})$ disappeared and the C=O vibrations at 1700-1800 cm⁻¹ became indistinguishable. This is a primary indication that propionic acid adsorbs on the catalyst surface as bidentate *via* the carboxylic group (**Figure 2-10**).

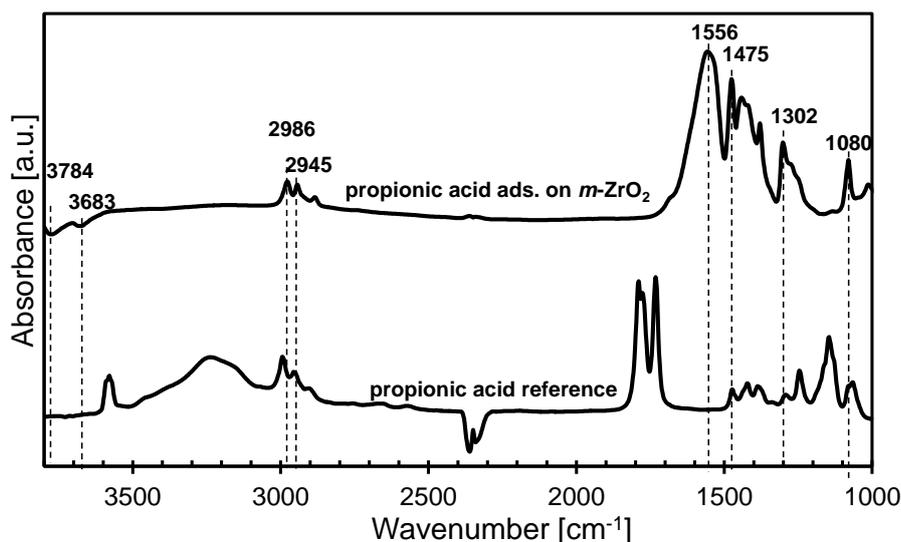

Figure 2-9. IR spectra of propionic acid (0.05 mbar) adsorbed on *m*-ZrO₂ at 40 °C and free propionic acid in vapor phase as reference.

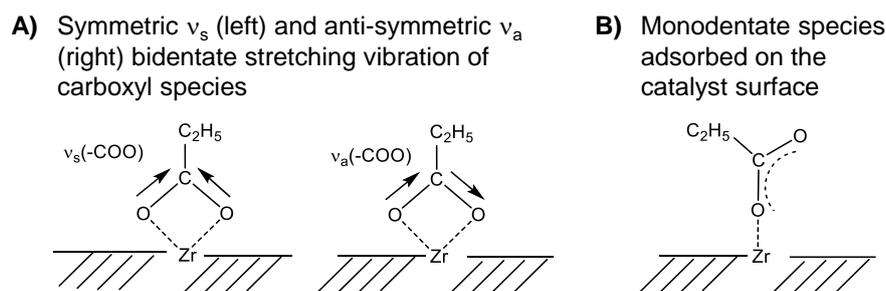

Figure 2-10. Adsorbed carboxyl species in **A)** bidentate and **B)** monodentate conformation on the surface of ZrO₂.

The bands at 1556 and 1419 cm⁻¹ are attributed to the O–C–O anti-symmetric (ν_a) and symmetric (ν_s) vibrations (**Figure 2-10, A**), which suggest the presence of a symmetric bidentate species with two indistinguishable O atoms. The band at 1419 cm⁻¹ (symmetric ν_s vibrations) may overlap with the more intense $\nu\text{-CH}_3$ vibration as part of the C–H triplet

(1400-1500 cm⁻¹).^{13c, 13d, 14} The bands for C–H vibrations remained unchanged at 2986 and 2945 cm⁻¹ as well as the vibrations of triplet (1400-1500 cm⁻¹) and ν -CH₃ (1080 cm⁻¹). This leads to the conclusion that when propionic acid is adsorbed on ZrO₂, the C=O vibrations at 1800 and 1700 cm⁻¹ and the C–O vibration at 1150 cm⁻¹ in free propionic acid disappear due to the formation of a surface carboxylate (**Figure 2-10, A**).

Figure 2-11 shows the IR spectra of propionic acid adsorbed on *m*-ZrO₂ and *t*-ZrO₂ at partial pressures 0.02-0.05 mbar and temperatures of 100-250 °C. The spectra are obtained by subtracting the activated ZrO₂ sample. With increasing pressure of propionic acid at 40 °C, the intensity of the characteristic bands on *m*-ZrO₂ (ν_a , ν_s , ν_{C-H} , δ -CH₃, ρ -CH₃) increased (**Figure 2-11, A**), while the intensity of the ZrO–H vibration decreased. The concentration of Zr–OH groups on the surface decreased as the acid adsorbed on the ZrO₂ surface. At the highest dosing pressure of 0.05 mbar, the peak at 1556 cm⁻¹ of propionic acid was split into two bands at 1583 and 1525 cm⁻¹. This suggests that propionate partially adsorbs in a monodentate configuration (**Figure 2-10, B**) which is characterized by a much larger splitting of the ν_a (COO) and ν_s (COO) carboxylate stretching frequencies.¹⁵ These adsorbate molecules are competing for the active sites of ZrO₂, monodentate dominates over bidentate at high pressures due to its lower space requirement. Near the reaction temperature of 250 °C (**Figure 2-11, B**), only ν_a (COO) and ν_s (COO) decreased markedly in intensity. At the elevated temperatures, more molecules were desorbed, lessening the surface coverage and competition by carboxylic acid for the active sites (*i.e.* oxygen vacancies). Accordingly, the splitting and difference of symmetric and asymmetric carboxylate stretching frequencies decreased, consistent with the bidentate configuration being dominant over the monodentate one. For propionic acid adsorbing on *t*-ZrO₂, principally the same species and vibration bands were observed. On increasing the pressure of propionic acid to 0.05 mbar at 40 °C (**Figure 2-11, C**), the intensity of the characteristic bands increased, indicating an increasing amounts of adsorbed molecules. Increasing the temperature caused the concentration of adsorbate to decrease (**Figure 2-11, D**).

The Ni/*m*-ZrO₂ and Ni/*t*-ZrO₂ catalysts showed the same trend upon adsorption of propionic acid as the bare supports, but the concentrations of adsorbed propionic acid was lower (**Figure A 2-5, A-D**). This is consistent with observations that the lower BET surface areas as well as the concentrations of acid sites for Ni/ZrO₂ are lower in comparison to the

bare ZrO₂ supports. The concentration of propionic acid adsorbed on the ZrO₂ and Ni/ZrO₂ catalyst surface was quantified *via* the peak area at 1080 cm⁻¹ ($\nu(\text{CH}_3)$). As shown in **Figure 2-12**, the coverage of propionic acid was generally much higher for the bare ZrO₂ supports than Ni/ZrO₂ samples. The adsorbed amount increased linearly as a function of the partial pressure of propionic acid from 0.02 to 0.05 mbar (**Figure 2-12, A**). The results also suggest that *m*-ZrO₂ adsorbed 1.5 times more propionic acid than *t*-ZrO₂ at 0.05 mbar and 40 °C, which in both cases expectedly decreased exponentially with temperature (**Figure 2-12, B**). The amount of propionic acid adsorbed on *m*-ZrO₂ and Ni/*m*-ZrO₂ was always more than that on *t*-ZrO₂ and Ni/*t*-ZrO₂, respectively. Due to this higher coverage and surface concentration, *m*-ZrO₂ is concluded to be the more active support for converting stearic acid, because the reaction order is positive in the reactant concentration. This is in good agreement with the experimental results above showing *m*-ZrO₂ to have the higher activity than *t*-ZrO₂.

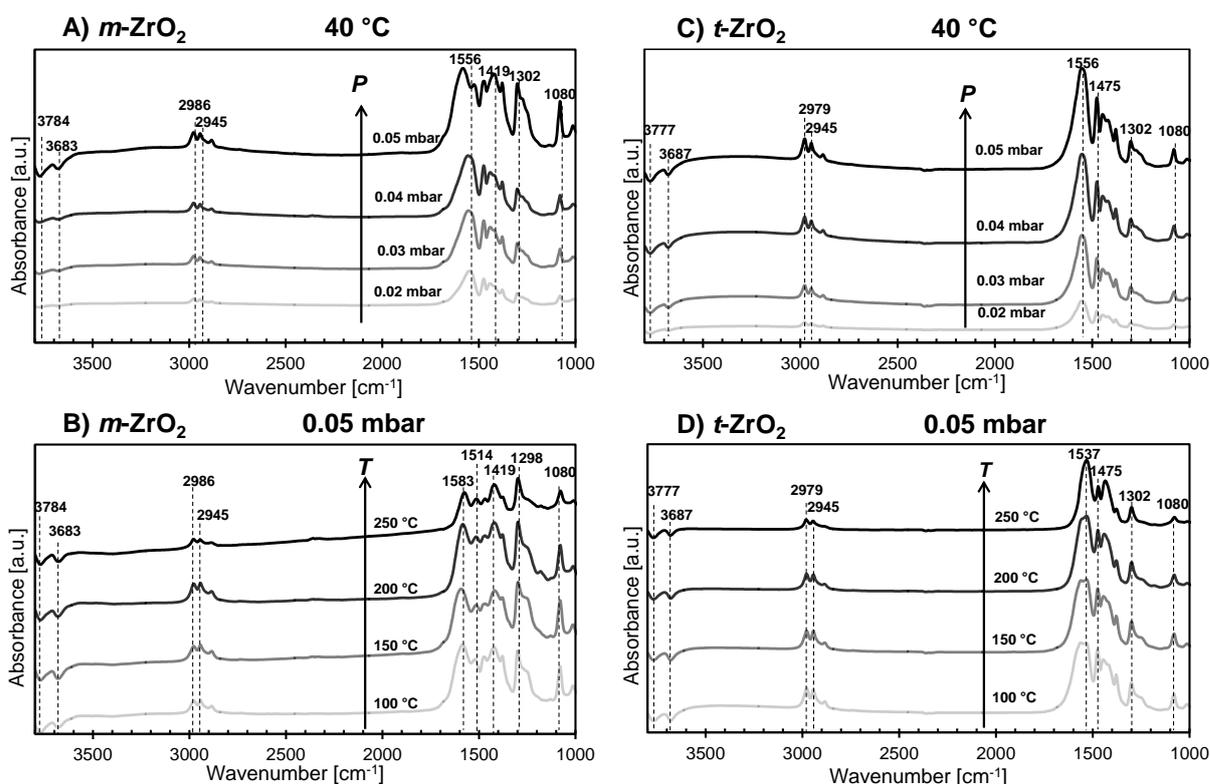

Figure 2-11. IR spectra of adsorbed propionic acid on *m*-ZrO₂ and *t*-ZrO₂, (**A** and **C**) with increasing pressures from 0.02 to 0.05 mbar at 40 °C, and (**B** and **D**) with increasing temperatures from 100 °C to 250 °C at 0.05 mbar pressure.

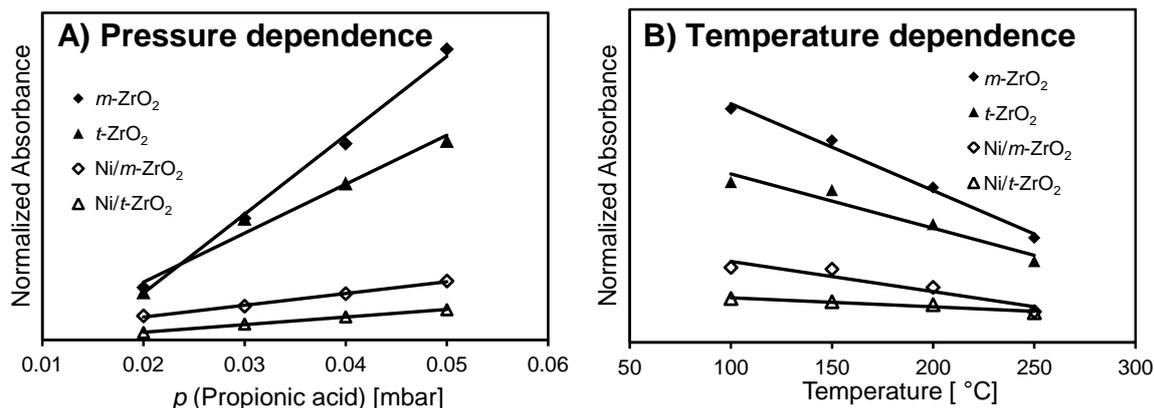

Figure 2-12. Adsorption of propionic acid on *m*-ZrO₂, *t*-ZrO₂, Ni/*m*-ZrO₂, and Ni/*t*-ZrO₂ as a function of **A)** partial pressure, and **B)** temperature determined by IR spectroscopy, shown as specific amount (peak area at $\nu = 1080 \text{ cm}^{-1}$) normalized by specimen mass.

2.3.8 Temperature programmed isotopic exchange (¹⁶O-¹⁸O) of *m*- and *t*-ZrO₂

Figure 2-13 shows the TPIE profiles for *m*-ZrO₂ and *t*-ZrO₂, respectively, where the mol% of ¹⁶O₂ (M32), ¹⁸O-¹⁶O (M34), and ¹⁸O₂ (M36) are presented as a function of temperature. The signal of ¹⁸O₂ with *m*-ZrO₂ (**Figure 2-13, A**) decreased from 2.5 to 1.0 mol%. This conversion on *m*-ZrO₂ is obviously much faster compared to *t*-ZrO₂ (**Figure 2-13, B**), which showed a small decrease of the ¹⁸O₂ signal from 2.5-2.0 mol%. Consistent with this, the concentration of ¹⁸O¹⁶O increased much faster with *m*-ZrO₂. The consumption and exchange of ¹⁸O₂ (M36) at *m*-ZrO₂ ($\Delta = 1.5 \text{ mol}\%$) was three times higher than on *t*-ZrO₂ ($\Delta = 0.5 \text{ mol}\%$), which parallels the difference in rates of stearic acid conversion on Ni/*m*-ZrO₂ and on Ni/*t*-ZrO₂. In summary, *m*-ZrO₂ shows higher activity towards ¹⁸O₂ exchange due to its higher concentrations of defect sites.¹⁶ Therefore, carboxylic acid adsorbs at the exchange sites of the catalyst to a much higher extent, as shown by IR spectroscopy, hence, leading to higher reactivity in the reduction of stearic acid.

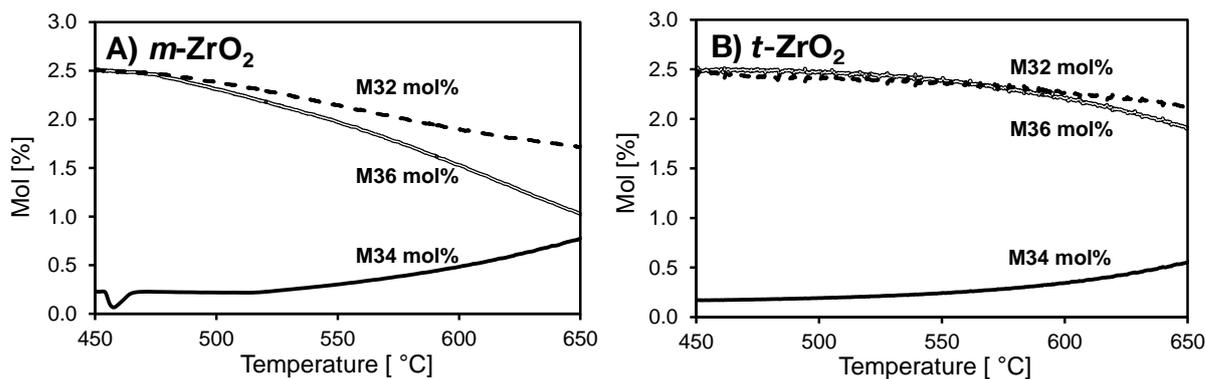

Figure 2-13. Temperature programmed isotopic exchange of ¹⁸O-¹⁶O with *m*-ZrO₂ **A**) and *t*-ZrO₂ **B**). Mol% of M32 (¹⁶O₂), M34 (¹⁸O-¹⁶O), and M36 (¹⁸O₂) as a function of temperature from 450 °C to 650 °C with a temperature increase interval of 5 °C·min⁻¹.

2.4 Conclusions

The ZrO₂ morphology of *m*-, *t*-, and *mix*-phases affects markedly the hydrodeoxygenation of stearic acid over Ni/ZrO₂ (with identical Ni particle sizes and distribution, as well as BET surface areas and acid and base site concentration) in dodecane. Ni/*m*-ZrO₂ has a three times higher activity towards stearic acid hydrogenation than Ni/*t*-ZrO₂ both selectively forming 1-octadecanol at low conversions. Surprisingly, this ratio agrees well with the ratio found for hydrogenation on bare *m*- and *t*-ZrO₂. Rate constants for Ni/ZrO₂ catalyzed stearic acid hydrogenation are comparable in the fitted and calculated individual measurement indicating very similar adsorption constants for reactants, intermediates, and products. The much lower (fitted) rate constant for decarbonylation of 1-octadecanol in the overall stearic acid hydrodeoxygenation is attributed primarily to competition of reactant and intermediates for sites in the conversion. The positive effect of *m*-ZrO₂ is concluded to be related to the substantially higher adsorbed concentration of the acid (concluded from the higher concentration of adsorbed propionic acid) on *m*-ZrO₂ compared to *t*-ZrO₂. The higher concentration of adsorbed reactants is related to the higher concentration of defect sites on the ZrO₂-surface as detected by the higher oxygen exchange ability of *m*-ZrO₂ support (quantified in the temperature programmed isotope exchange experiment). The results show that it is possible to enhance reactivity for the reductive conversion of fatty acids by maximizing the concentration of oxygen defects sites.

2.5 Experimental Section – Materials and Methods

2.5.1 Chemicals

All chemicals, *i.e.*, Zr(OH)₄ × H₂O (XZO 1247/01, MEL Chemicals), ZrO(NO₃)₂ × x H₂O (Sigma-Aldrich, 99%), methanol (Sigma-Aldrich, 99%), urea (Grünning, 99.5%), Ni(NO₃)₂·6 H₂O (Acros Organics, ≥98.5%), stearic acid (Sigma-Aldrich, ≥99.5% analytical standard), 1-octadecanol (Sigma-Aldrich, ≥99.5% Selectophore™), *n*-octadecane (Sigma-Aldrich, 99%), *n*-heptadecane (Sigma-Aldrich, 99%), dodecane (Sigma-Aldrich, ≥99%, *ReagentPlus*), propionic acid (Sigma-Aldrich, ACS grade ≥99.5%) were purchased commercially and were not further purified.

2.5.2 Catalyst preparation

Three types of ZrO₂ supports were synthesized. Mix-phase ZrO₂ was prepared by calcination of Zr(OH)₄·H₂O at 400 °C in ambient air for 4 h. *Monoclinic*- and *tetragonal*-ZrO₂ were prepared by the solvothermal method by mixing ZrO(NO₃)₂ with water and methanol, respectively.¹⁷ An aqueous or methanolic solution of ZrO(NO₃)₂ (0.6 mol·L⁻¹) was added with urea (urea/Zr = 10:1). The solvothermal reaction was performed in a stainless-steel autoclave with Teflon® liner at 160 °C and autogenous pressure for 21 h. After washing five times the precipitate with H₂O or MeOH, it was dried overnight at 110 °C and then ground and calcined in air at 400 °C for 4 h at a heating rate of 2 °C·min⁻¹ (flow rate: 100 mL·min⁻¹).

The 10 wt% Ni/ZrO₂ catalysts were prepared by impregnation. Ni(NO₃)₂·6 H₂O (3.30 g) was dissolved in deionized H₂O (5.0 g), and the resulting solution was added dropwise to the support under stirring in ambient air. The slurry was further stirred for 4 h, followed by drying at 110 °C overnight. Subsequently, the ground solid was calcined in synthetic air (flow rate: 100 mL·min⁻¹) at 450 °C for 4 h (heating rate: 2 °C·min⁻¹) and reduced in H₂ flow (flow rate: 100 mL·min⁻¹) at 500 °C for 4 h (heating rate: 2 °C·min⁻¹).

2.5.3 Catalyst characterization

X-ray powder diffraction (XRD) was performed on Philips X'Pert Pro System equipped with a Cu K α radiation source (40 kV/45 mA) with 1.08 ° min⁻¹ in the 2 θ range of 5-70 °. The ratio of *monoclinic* and *tetragonal* phases in *mix-ZrO₂* was determined by **Equation 2-6** using the integrated intensities of the (111) and (11-1) reflecting *monoclinic* and *tetragonal* XRD patterns, respectively.¹⁸ The (111)_m and (11-1)_m reflections for the *monoclinic* phase are at 2 θ of 31.4 ° and 28.3 °, respectively, while the (111)_t reflection from *tetragonal* phase is at 2 θ of 30.4 °. Accordingly, the actual ratio of *monoclinic* to *tetragonal* ZrO₂ in the physically mixed Ni/*m:t*-ZrO₂ was determined using **Equation 2-6** after fitting and integrating the corresponding peaks from the XRD (**Figure A 2-1, B** and **Figure A 2-6**).

Equation 2-6

$$x_m = \frac{I(1\bar{1}\bar{1})_m + I(111)_m}{I(1\bar{1}\bar{1})_m + I(111)_m + I(111)_t}$$

Atomic absorption spectroscopy (AAS) was used to determine the Ni content of the catalysts with a UNICAM 939 AA-Spectrometer. Prior to measurement, the sample was dissolved in boiling concentrated hydrofluoric acid.

The **BET** surface area was determined by adsorption-desorption with nitrogen at -196 °C using a Sorptomatic 1990 series instrument. The sample was activated in vacuum at 250 °C for 2 h before measurement.

The **EDX** mappings were obtained using a JEM-ARM200CF operated at 200 kV with an integrated probe aberration (Cs) corrector and a cold-field emission gun (CFEG) electron source. After reduction the finely ground powdered catalyst samples were stored and mounted under Ar atmosphere.

Temperature programmed desorption (TPD) of ammonia and carbon dioxide was carried out in a 6-fold parallel reactor system. The pressed samples (500-710 μ m) were firstly activated in He at 500 °C for 1 h and loaded with the adsorbent NH₃ or CO₂ at a partial pressure of 1 mbar and 100 °C or 40 °C, respectively. The samples were then purged with

He for 1 h in order to remove physisorbed species. After activation, the six samples were heated from 100-770 °C with a rate of 10 °C·min⁻¹ to desorb NH₃ and from 40 to 700 °C to remove CO₂, and the signals were detected by a Balzers QME 200 mass spectrometer.

Temperature programmed reaction (TPR) with H₂ was performed in a packed bed flow reactor equipped with a mass spectrometer. First, 100 mg calcined Ni/ZrO₂ catalyst (250-400 μm) was activated in He at 200 °C (heating rate 10 °C·min⁻¹) for 30 min. and cooled to ambient temperature. The reduction was carried out from ambient temperature to 800 °C (heating rate: 10 °C·min⁻¹) and maintaining 800 °C for 30 min in 10% H₂/He mixture gas (2 mL·min⁻¹ H₂/18 mL·min⁻¹ He). The amount of water produced in the reaction was determined by an online mass spectrometer.

IR spectroscopy of adsorbed propionic acid was performed on a Bruker VERTEX 70 spectrometer at a resolution of 2 cm⁻¹ with 128 scans in the range of 400-4000 cm⁻¹. For the measurements, the samples were pressed into self-supporting wafers and mounted in the sample holder. The ZrO₂ samples were activated in vacuum ($p = 10^{-7}$ mbar) at 300 °C for 1 h. The Ni/ZrO₂ catalysts were activated in H₂ at 400 °C for 1 h, and then subsequently outgassed under vacuum ($p = 10^{-7}$ mbar) to remove H₂ while cooling to 40 °C. The adsorption of propionic acid was performed from 0.01 to 0.05 mbar until equilibrium was reached. In addition, the effect of temperature was investigated by heating the cell stepwise up to 250 °C. The IR spectra of adsorbed propionic acid were obtained by subtracting the activated sample, and then were normalized by the weight of sample wafer.

The **near-edge structure (XANES)** and extended **X-ray absorption fine-structure (EXAFS)** measurements were performed in transmission mode at the Pacific Northwest Consortium/X-ray Science Division (PNC/XSD) bending-magnet beamline at Sector 20 of the Advanced Photon Source (APS) at Argonne National Laboratory (ANL). Both Ni (8331.5 eV) and Zr (17995.88 eV) K-edge spectra were acquired. A combination of monochromator detuning (10%) and a harmonic rejection mirror placed upstream of the I_0 detector reduced contributions from higher harmonics. A Ni or Zr foil was placed downstream of the sample cell as a reference to calibrate the photon energy of each spectrum. Typically, two 15 min scans (Ni-edge spectra) and four 15 min scans (Zr-edge spectra) were averaged to generate the spectra. The catalyst samples were ground and mixed with boron nitride (catalyst:boron nitride, 20:80 wt%, 5:95 wt% for Ni- and Zr-edges, respectively), then pressed into 5 × 12 mm pellets (80 mg) and mounted onto a multiple sample holder.

ATHENA software package¹⁹ was used to remove the background from the $\chi(k)$ oscillations. The Fourier transform of the k -space EXAFS data (both real and imaginary parts of $\chi(R)$) were fitted to a theoretical model (FEFF9) calculated using the ARTEMIS software package. A starting point for evaluating the nanoparticle structure was the measurement of reference standards including bulk (fcc) NiO, bulk (hcp) α -Ni(OH)₂, and bulk (fcc) Ni using literature values for their lattice parameters.²⁰ A combination of different single and multiple photoelectron scattering paths were used to fit the first 5 shells of the NiO, α -Ni(OH)₂, and Ni nanoparticles.²¹ For samples containing both oxidation states, the structural parameters were constrained and then the percentage of each phase was fitted. As a starting point for modeling the ZrO₂ nanoparticles, crystalline m -ZrO₂ and bulk t -ZrO₂ structures derived from their lattice parameters were used.²² Single scattering paths of Zr and O for the *monoclinic* and *tetragonal* phase were fitted according to Rush *et al.*²³

For the **temperature programmed isotope (¹⁸O₂ – ¹⁶O₂) exchange** of m - and t -ZrO₂, 100 mg of the pelletized supports (500-710 μ m) were diluted in 300 mg of SiC and packed into a fixed-bed reactor (inner diameter 4 mm). After outgassing the samples for 2 h at 450 °C in 10 mL·min⁻¹ of He, ¹⁸O₂ and ¹⁶O₂ were fed simultaneously (each 2.5 mol%) while increasing the temperature to 650 °C (5 °C·min⁻¹). The atomic mass units of 32 (¹⁶O₂), 34 (¹⁸O¹⁶O) and 36 (¹⁸O₂) in the product stream were recorded as a function of time by a Pfeiffer OmniStar™ GSD 320 OC mass spectrometer.

2.5.4 Measurement of the catalytic activity

For a typical experiment to convert stearic acid or 1-octadecanol 1.0 g of the reactants and 0.1 g catalyst were mixed with 100 mL dodecane, loaded into the reactor (Parr, 300 mL), and then purged three times with H₂. The reaction was carried out at 260 °C in presence of 40 bar H₂ for 2 h at a stirring speed of 600 rpm. *In situ* sampling was performed every 20 min., and the liquid samples were analyzed by a Shimadzu 2010 GC-MS using a HP-5 capillary column (30 m, 0.32 mm inner diameter, 0.25 μ m film) equipped with a flame ionization detector (FID). Reproducibility of the rates has been better than \pm 5% for all experiments.

2.6 Acknowledgements

Financial support of Sebastian Foraita, Eszter Baráth, and Chen Zhao in the framework of AlgenFlugKraft project, Bavarian Ministry of Economic Affairs and Media, Energy and Technology (Bayerisches Staatsministerium für Wirtschaft und Medien, Energie und Technologie) and Bavarian State Ministry of Education, Science and the Arts (Bayerisches Staatsministerium für Bildung und Kultus, Wissenschaft und Kunst), is highly appreciated. Support of Pinghong Xu to take TEM images was provided by the United States (US) Department of Energy (DOE) Grant No. DE-FG02-03ER46057 through the University of California at Davis. Use of TEM was supported under the Laboratory Directed Research and Development Program: Chemical Imaging Initiative at Pacific Northwest National Laboratory (PNNL), a multi-program national laboratory operated for DOE by Battelle under Contract DE-AC05-76RL01830. TEM was performed at EMSL, a DOE Office of Science user facility sponsored by the Office of Biological and Environmental Research and located at PNNL. XAFS measurements and related work performed by John L. Fulton, Zizwe A. Chase, and Donald M. Camaioni were supported by the US DOE Office of Science, Office of Basic Energy Sciences (BES), Division of Chemical Sciences, Geosciences & Biosciences. PNC/XSD facilities at the Advanced Photon Source (APS), and research at these facilities, are supported by DOE/BES, the Canadian Light Source and its funding partners, the University of Washington, and the APS. Use of the APS, an Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory, was supported by the DOE under Contract No. DE-AC02-06CH11357. The assistance of Dr. Nigel Browning (PNNL) in performing TEM and Dr. Mahalingam Balasubramanian (APS) in performing XAFS measurements is highly appreciated. Thank deserves to Franz-Xaver Hecht for N₂-sorption and Martin Neukamm for AAS measurements, and the help provided by Robin Kolvenbach for kinetic fitting, and Christian A. Gärtner for isotopic exchange (¹⁶O–¹⁸O) experiments is gratefully acknowledged.

2.7 Contributions

Sebastian Foraita synthesized all samples, designed, performed and analyzed the experiments, maintained the reactor and the sample analysis (GC-MS) and prepared and edited

the manuscript. John L. Fulton and Donald M. Camaioni contributed by planning, the execution and analyzing the XAFS measurements, scientific discussions and correcting the manuscript. Zizwe A. Chase wrote the XAFS part of the publication. Aleksei Vjunov supported in carrying out the XAFS measurements. Pinghong Xu took EDX-TEM images. Eszter Baráth contributed by discussing the results and correcting the manuscript. Chen Zhao supported in planning the first experiments, scientifically discussing the results and correcting the manuscript. Johannes A. Lercher was supervising the whole research, discussing the results scientifically and correcting the manuscript.

Hydrothermally synthesized SiO₂-ZrO₂ mixed oxide has novel nano-layers possessing Brønsted acid sites and high specific surface area. Used as supports for Ni catalyst, they enhanced the activity for fatty acid reduction compared to Ni/ZrO₂.

Keywords: Hydrodeoxygenation • Decarbonylation • SEM • IR Spectroscopy • SiO₂-ZrO₂ mixed Oxide

3.1 Abstract

A series of SiO₂-ZrO₂ mixed oxide with varying SiO₂ concentrations was hydrothermally synthesized and used as support for Ni in the hydrodeoxygenation of stearic acid. ZrO₂ provides a relatively low surface area and only Lewis acid sites, and Ni supported on ZrO₂ produces *n*-heptadecane from stearic acid *via* hydrogenation and decarbonylation. The SiO₂-ZrO₂ mixed oxides have a higher specific surface area as well as a novel spherical and nano-layer shaped morphology. Brønsted acid sites are created by incorporation of SiO₂ into ZrO₂ promoting the hydrodeoxygenation activity of Ni and specifically opening a new reaction route to *n*-octadecane *via* the dehydration of 1-octadecanol intermediate into 1-octadecene with subsequent hydrogenation.

3.2 Introduction

The high growth rates and oil content, as well as the independence from arable land make microalgae the ideal basis for third-generation biofuels.¹ The conversion of algae oil into hydrocarbon transportation fuel requires removing of oxygen from triglycerides. This can be achieved using commercially available sulfide catalysts, *e.g.* NiMoS/Al₂O₃, and existing hydrotreating infrastructure.² However, the sulfide catalysts are not ideal for the conversion of the nearly sulfur-free triglycerides, because they deactivate *via* sulfur elimination and contaminate the product stream with organic sulfides.³

Supported noble metal Ru, Pd and Pt catalysts overcome such disadvantages offering high activity and selectivity for hydrodeoxygenation of triglycerides and fatty acids, but are rather expensive.⁴ A more economic alternative would be tungsten carbide based catalysts, however, their performance has not been able to reach the performance of commercial hydrotreating catalysts (NiMo/Al₂O₃).⁵

In order to directly convert microalgae oil to diesel-range hydrocarbons at 260 °C and 40 bar H₂, two types of novel sulfur-free Ni based catalysts were developed.⁶ The catalytic process starts with fast hydrogenolysis into propane and fatty acids followed by slower hydrodeoxygenation of the fatty acids into alkanes.^{6a} The conversion of fatty acids, *e.g.* stearic acid, on Ni/ZrO₂ occurs *via* two pathways, one catalyzed solely by Ni and one catalyzed synergistically by Ni and the ZrO₂ support, both leading to an alkane with one carbon

less than the fatty acid, *i.e.*, *n*-heptadecane (C₁₇) from stearic acid (C₁₈). On Ni, the fatty acid is hydrogenated to the aldehyde, followed by decarbonylation of the aldehyde to an alkane. On ZrO₂, α -H abstraction and elimination of H₂O from the fatty acid adsorbed on the oxygen vacancies leads to a ketene intermediate, which is further hydrogenated to an aldehyde that decarbonylates to an alkane on Ni.⁷

Generally, ZrO₂ is an excellent catalytic support, *inter alia* due to its high hydrothermal stability.⁸ The relatively low specific surface area poses some drawbacks, as the sites involved in the hydrodeoxygenation pathway on ZrO₂ contribute markedly to the overall conversion. The incorporation of SiO₂ has been reported to enhance the specific surface area of ZrO₂⁹ through formation of a mixed oxide phase, and can additionally induce Brønsted acid sites.¹⁰ It has been shown previously that the presence of Brønsted acid sites in proximity to Ni in zeolites enhances the hydrogenation activity.¹¹

Therefore, the general applicability of the concept of rate enhancement by introducing Brønsted acid sites *via* SiO₂-ZrO₂ mixed oxides on the support for Ni with respect to the hydrodeoxygenation of stearic acid, one of the most abundant fatty acids from algae oil, was explored. It was hypothesized that the combination of the large pore Brønsted acid support with Ni as hydrogenation catalyst function may lead to high activity and high selectivity retaining all carbon atoms in the fatty acid.

3.3 Results and Discussion

The catalytic properties of two types of Ni catalysts, prepared by wet impregnation on hydrothermally synthesized and impregnated SiO₂-ZrO₂ supports are investigated. For details of the preparation procedure please see experimental part (page 74).

3.3.1 Catalyst characterization

The **X-ray powder diffractogram (XRD)** of the ZrO₂ samples, prepared by the hydrothermal synthesis (H), are presented in **Figure 3-1**. The diffractogram of unmodified *monoclinic* ZrO₂ (*m*-ZrO₂) with its characteristic diffraction pattern is shown as well for comparison. It shows the expected diffraction peaks at 24.5, 28.3, 31.6 and 34.5° with a

shoulder at 35.3° (JCPDS card No. 37-1484).¹² With increasing SiO₂-content, the peak intensity (6 SiO₂-ZrO₂ (H)) decreased, suggesting lower crystallinity. In parallel, the crystal phase of ZrO₂ changed from *monoclinic* to a new phase (27 SiO₂-ZrO₂ and 37 SiO₂-ZrO₂ (H)), which has been assigned to *tetragonal* ZrO₂ in literature.^{12c, 12d} Above 40 wt% SiO₂, only broad signals characteristic for amorphous oxides¹³ were observed, while diffraction peaks of either *monoclinic* or *tetragonal* ZrO₂ were absent, implying an amorphous structure of the resulting materials.¹⁴ In line with that, the peak attributed to pure SiO₂ was lowered in intensity. Presumably, this is the result of atomic dispersion in mixed SiO₂-ZrO₂ where Zr-O units are alternating with SiO₄-tetrahedra. In contrast, the diffraction patterns remain identical when the ZrO₂ is modified by impregnation with SiO₂, indicating the crystal structure of ZrO₂ is not affected by SiO₂ (**Figure 3-2**).

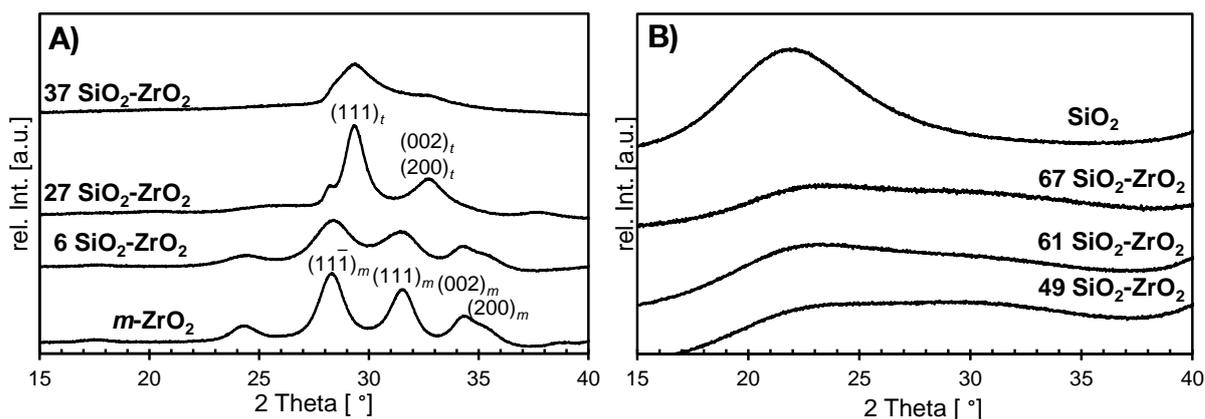

Figure 3-1. XRD patterns of ZrO₂ modified with increasing concentrations of SiO₂ by the hydrothermal method. **A)** 0-37 mol% SiO₂. **B)** 49-100 mol% SiO₂.

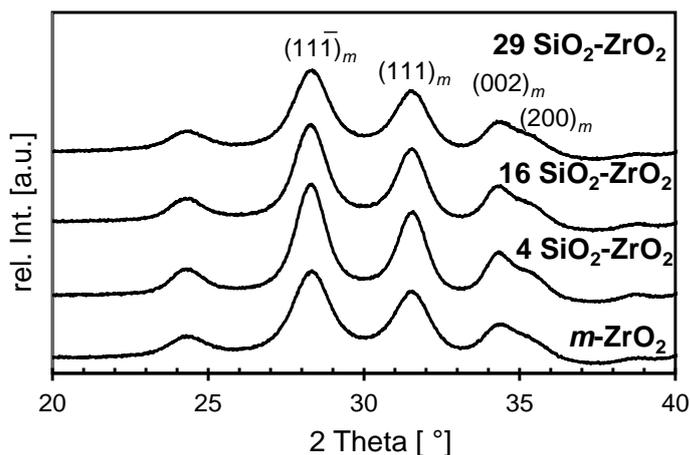

Figure 3-2. XRD patterns of ZrO₂ modified with increasing amount of SiO₂ by impregnation method (0-29 mol%).

High Resolution Scanning Electron Microscopy (HR-SEM)

The highly increased specific surface area of the materials prepared by the hydrothermal method is also manifested in the HR-SEM micrographs. While unmodified ZrO₂ (**Figure 3-3**, upper left) showed particles with several micrometers in diameter, the surface of ZrO₂-SiO₂ is more faceted, forming nano-layers with increasing content of SiO₂. For 37 SiO₂-ZrO₂, highly organized structures with a primary particle size of 1 μm are formed. Nano layers arrange in a way that spheres with sponge like morphologies are formed. Similar structures were reported by Faria *et al.*¹⁵ The 67 ZrO₂-SiO₂ had an extraordinary morphology, in which the excess SiO₂ not incorporated into ZrO₂ was deposited on the surface of the lamellar structure as SiO₂-nanoparticles with a size of 10 nm (**Figure 3-3**, bottom right). In contrast, the SiO₂ *impregnated* ZrO₂ samples did not show such a change in morphology and were comparable in shape to the reference material independent of the degree of the SiO₂ loading (**Figure 3-4**). The silica deposits are visible on the ZrO₂ surface.

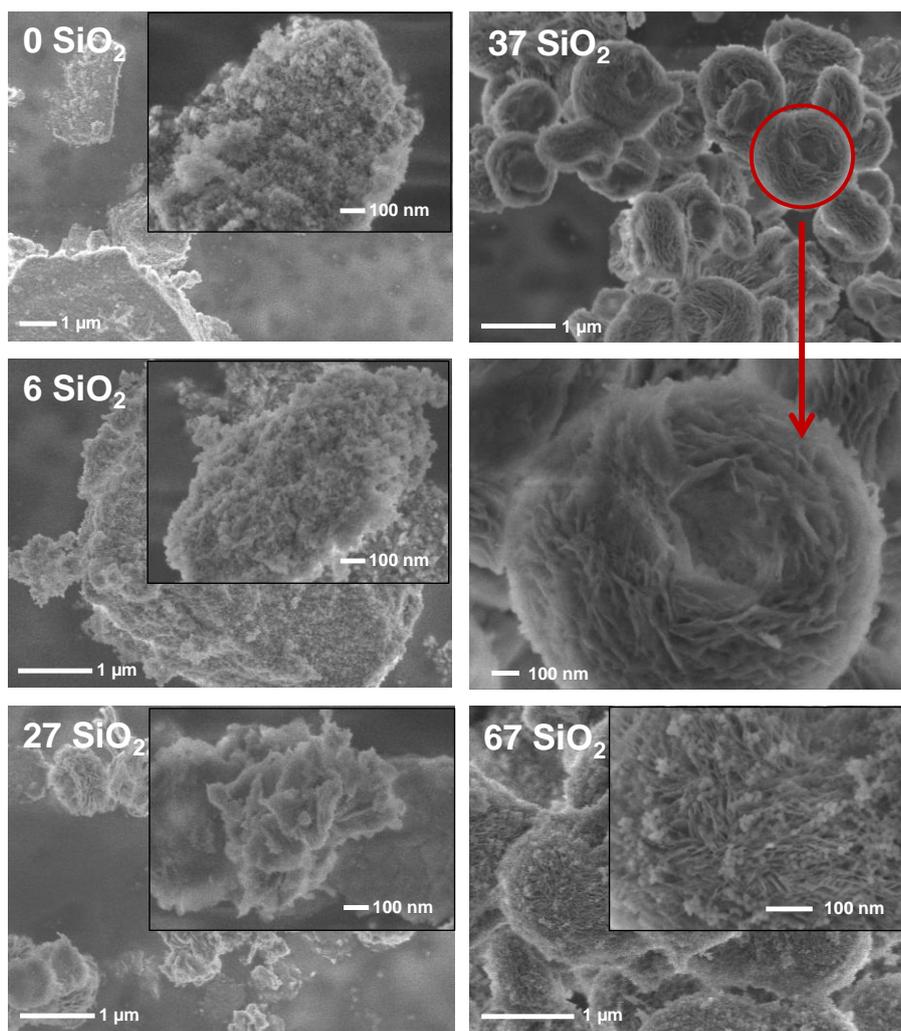

Figure 3-3. High resolution scanning electron microscopy (HR-SEM) images of untreated ZrO₂ (0 mol% SiO₂), 6 SiO₂-ZrO₂, 27 SiO₂-ZrO₂, 37 SiO₂-ZrO₂, 67 SiO₂-ZrO₂ prepared by *one-pot* hydrothermal method.

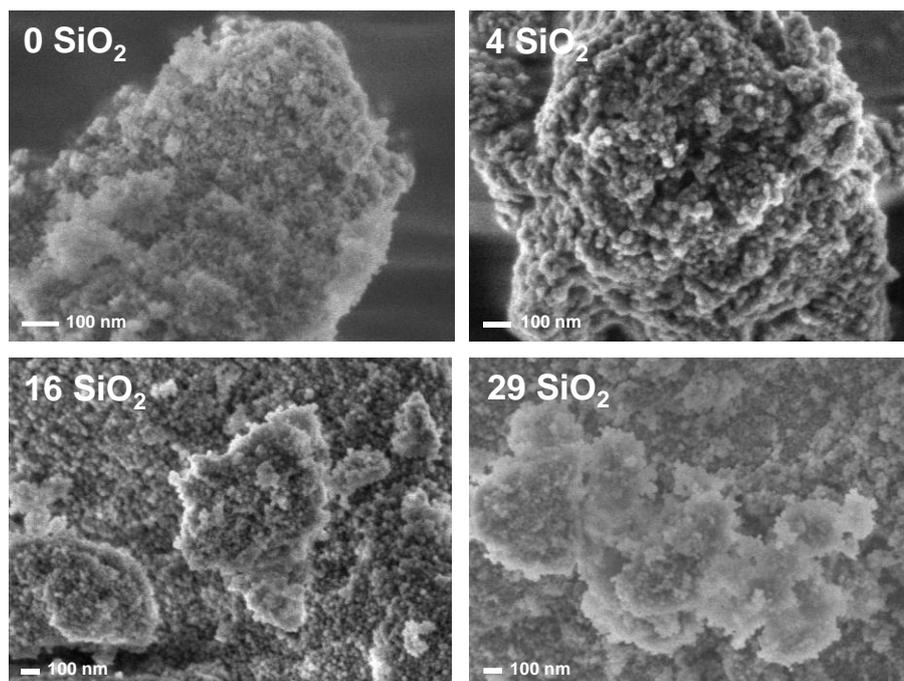

Figure 3-4. HR-SEM images of untreated ZrO₂ (0 mol% SiO₂) and ZrO₂ impregnated with SiO₂ at increasing loadings.

Physicochemical properties

As shown in **Table 3-1**, with the increase of SiO₂ concentration, the BET surface areas of the Ni/SiO₂-ZrO₂, determined by N₂ physisorption, increased from 72 m²·g⁻¹ for Ni/*m*-ZrO₂ to 193 m²·g⁻¹ for Ni/37 SiO₂-ZrO₂, significantly higher than reported before,¹⁶ while it afterwards decreased to 67 m²·g⁻¹ for Ni/67 SiO₂-ZrO₂, which is close to the value for Ni/SiO₂. The high BET surface area for Ni/37 SiO₂-ZrO₂ (193 m²·g⁻¹) is due to the small crystal size, which was only 2.5 nm compared to 7.1 nm of *m*-ZrO₂ (**Table A 3-1, Appendix**, page 79). In contrast, the catalysts prepared by the SiO₂-impregnation method only had specific surface areas between 71-97 m²·g⁻¹ (**Table 3-2**).

Ni/29 SiO ₂ -ZrO ₂	97	9.9	3.6	28	0.16	0.10

[a] Number in the label is mol% SiO₂. [b] Determined by Ni-AAS. [c] Dispersion (D) and particle size (d) were determined by H₂-Chemisorption. [d] Determined by TPD of NH₃. [e] Determined by TPD of CO₂.

The concentration of acid sites were always lower for the Ni-impregnated catalysts than for the parent supports (compare **Table 3-1** with **Table A 3-1** and **Table 3-2** with

Table A 3-2). The acid site concentration increased from 0.15 to 0.34 mmol·g⁻¹ for Ni/ZrO₂ to Ni/27 SiO₂-ZrO₂ (H) and decreased to 0 for Ni/SiO₂ (**Table 3-1**). The concentration of acid sites for the Ni-catalysts, modified by SiO₂-impregnation was constant at 0.16 mmol·g⁻¹ (**Table 3-2**) and was lower than that of the corresponding parent support (**Table A 3-2**). This indicates that the ZrO₂ surface and its acid sites are partially blocked by SiO₂. With the increase of the SiO₂ content, the basic site concentration for the mixed oxides prepared with the hydrothermal method decreased from 0.25 to 0 mmol·g⁻¹, and that for the SiO₂ impregnated samples decreased from 0.19 to 0.10 mmol·g⁻¹, in line with similar studies on SiO₂-ZrO₂ mixed oxides by Yamaguchi *et al.*¹⁷

IR spectra of adsorbed pyridine

In **Figure 3-5** the IR spectra of adsorbed pyridine are shown for unmodified *monoclinic* ZrO₂, SiO₂-ZrO₂ (37 SiO₂-ZrO₂, H), SiO₂-impregnated ZrO₂ (29 SiO₂-ZrO₂, Imp.) and a pure SiO₂ reference. The ZrO₂ showed the bands of pyridine adsorbed on Lewis acid sites (LAS) at 1610 and 1448 cm⁻¹ (**Figure 3-5, A**). SiO₂-ZrO₂ showed emerging peaks at 1630 and 1547 cm⁻¹ attributed to pyridinium ions formed by adsorption on Brønsted acid sites (BAS). The band at 1462 cm⁻¹ is attributed to pyridine coordinately adsorbed on Lewis acid sites (LAS), the band at 1491 cm⁻¹ to pyridine adsorbed on both strong LAS and BAS.¹⁸ **Table 3-3** shows the quantification of BAS and LAS for 27 SiO₂-ZrO₂ (H) and 37 SiO₂-ZrO₂ (H). 27 SiO₂-ZrO₂ (H) had the highest total concentration of acid sites (0.93 mmol·g⁻¹), and 37 SiO₂-ZrO₂ (H) has the highest concentration of BAS (0.36 mmol·g⁻¹). In contrast, the impregnated material (29 SiO₂-ZrO₂, Imp.) showed adsorption on identical sites as on ZrO₂, but in lower concentrations. This is attributed to the fact that ZrO₂ is partially covered by SiO₂, leading to fewer accessible Lewis acid sites. Finally, the pure SiO₂ reference did not adsorb significant concentrations of pyridine after evacuation at 150°C.

The broad peaks at 3774 and 3680 cm⁻¹ (**Figure 3-5, B**) are assigned to the stretching vibrations of terminal and bridging surface OH groups of Zr, respectively, that disappear upon adsorption of pyridine and are visible as negative peaks in the difference spectra.^{16b, 18d, 19} The band at 3735 cm⁻¹ (37 SiO₂-ZrO₂ (H) and 29 SiO₂-ZrO₂ Imp.) is attributed to isolated SiOH groups.^{18a, 20}

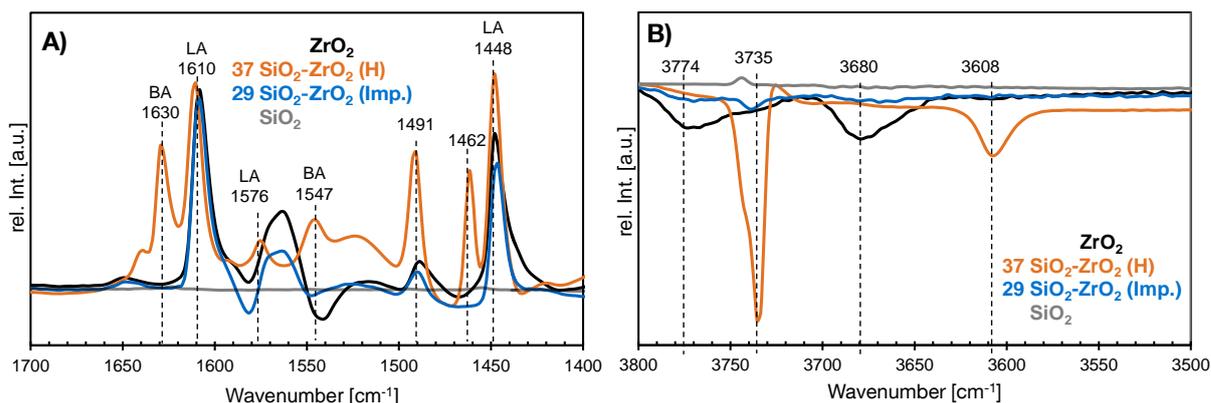

Figure 3-5. IR spectra of pyridine adsorbed on ZrO₂ (black), 37 SiO₂-ZrO₂ (*one-pot* hydrothermal synthesis) in orange, 29 SiO₂-ZrO₂ (Impregnation) in blue and SiO₂ reference (gray). **A)** Pyridine vibrations region (1700-1400 cm⁻¹) **B)** Surface Zr-OH and Si-OH stretching vibration region (3800-3500 cm⁻¹).

Table 3-3: Concentration of Brønsted and Lewis acid sites quantified by IR spectra of adsorbed pyridine.

Ni/27 SiO ₂ -ZrO ₂	930	136	794
Ni/37 SiO ₂ -ZrO ₂	730	356	374

The IR spectra of adsorbed pyridine for all samples prepared by the *one-pot* hydrothermal synthesis method with different SiO₂-contents are compared in **Figure 3-6, A**. As indicated in the previous paragraph, the spectrum of bare ZrO₂ and 6 SiO₂-ZrO₂ showed broad bands with low intensities at 3774 and 3680 cm⁻¹ that are attributed to ZrOH groups (**Figure 3-6, B**). For higher contents of SiO₂ (27-61 mol%), bands at 3745-3735 cm⁻¹ appeared that correspond to isolated SiOH groups. Like SiO₂, the mixed oxide with the highest SiO₂-content (69 SiO₂-ZrO₂) showed negligible adsorption of pyridine. The peak at 3608 cm⁻¹ that only appeared for 27-SiO₂-ZrO₂ and 37 SiO₂-ZrO₂, should be highlighted, which also had the highest concentrations of BAS. This band at 3608 cm⁻¹ is similar in wavenumber to the bridging OH groups in zeolites²¹ responsible for the high Brønsted acid strength. Brønsted acid sites were suggested to be present in SiO₂-ZrO₂ as well (**Scheme 3-1, A**).^{21c, 22} However, in a classic substitution model this would require a sufficient number of Zr³⁺-cations²³, which are unlikely to be formed under the conditions employed.²⁴ Therefore,

a structure (**Scheme 3-1, B**) based on Pauling's electrostatic valence rule is tentatively proposed.²⁵ The coordination number (CN) of Zr in tetragonal ZrO₂, which is the dominating phase in the presence of SiO₂, is eight, whereas the CN(Si) = 4 in SiO₂. The incorporation of SiO₂ into the ZrO₂ structure and, thus, the formation of a mixed oxide lead to an undercoordination of the surface oxygen for ZrO₂ rich samples. This is hypothesized to be balanced by a proton, leading to an OH band at 3608 cm⁻¹ accounting for the Brønsted acid site.²⁶ With increasing SiO₂-content, the incorporation cannot be stabilized, resulting in phase segregation and a lower concentration of BAS.

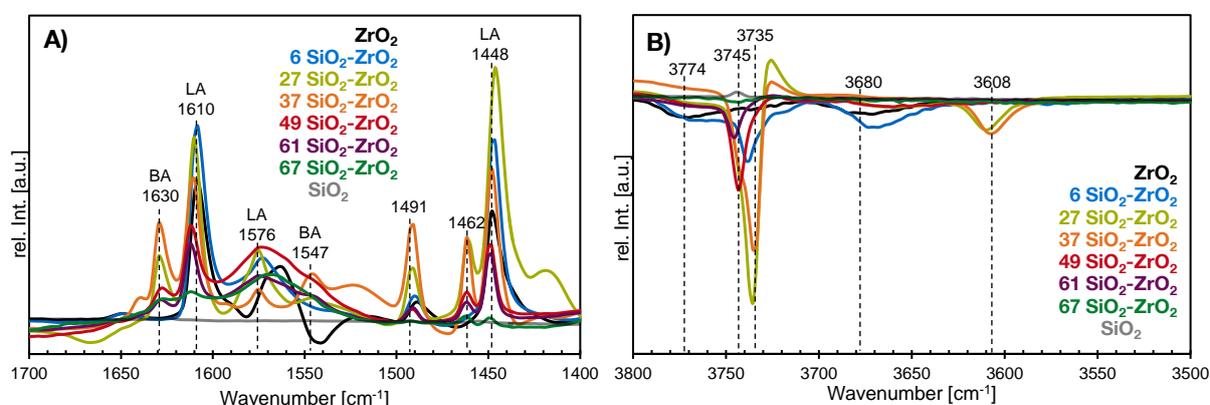

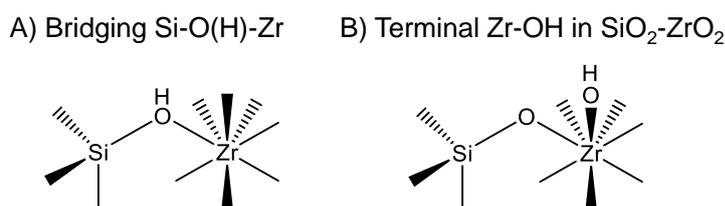

Figure 3-6. IR spectra of pyridine adsorbed on SiO₂-ZrO₂ (*one-pot* hydrothermal synthesis) with varying mol% SiO₂. **A)** Pyridine vibrations region (1700-1400 cm⁻¹) **B)** Surface Zr-OH and Si-OH stretching vibration region (3800-3500 cm⁻¹).

Scheme 3-1. Schematic representation of bridging OH and terminal OH group of Si-O-Zr in mixed oxide SiO₂-ZrO₂.

The model is derived from the considerations of Tanabe^{10b}, taking into account the coordination numbers of both cations and anions. According to this model, all oxygen anions are assumed to maintain the coordination number of the major oxide component. In contrast to that, the metal cations may retain the coordination number of their pure metal oxides for both major and minor component. This leads to an excess charge in a model structure. If the excess charge is negative, it has to be balanced by a proton generating a BAS. Accordingly,

a positive excess charge leads to the introduction of an oxygen vacancy, and hence to a LAS. The simultaneous occurrence of BAS and LAS, like here, may point to the existence of domains with varying concentrations of the constituents.²⁷ Note that such a model is in agreement with the Sanderson electronegativity concept²⁸ and the mixing rule.²⁹

²⁹Si-NMR Spectroscopy

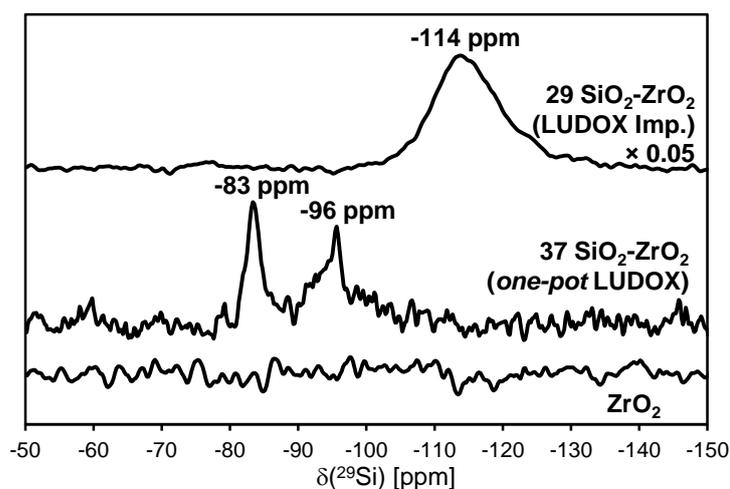

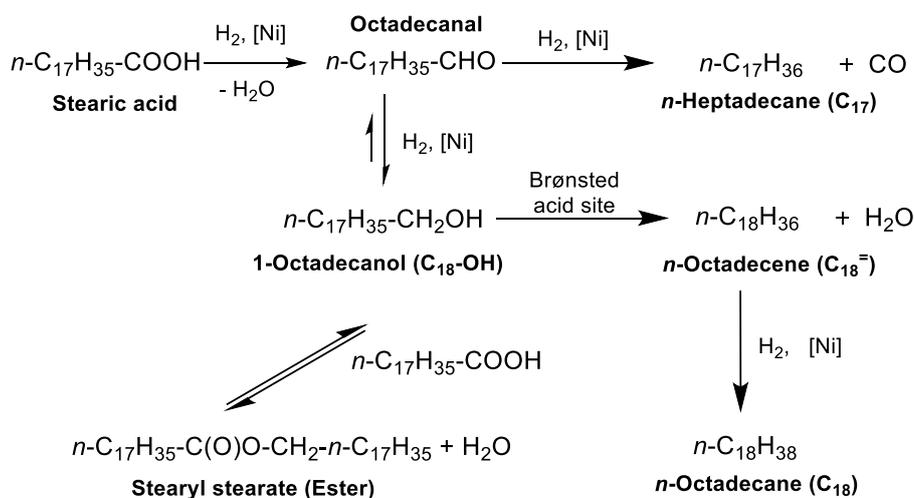

Figure 3-7. ²⁹Si-MAS-NMR spectra of ZrO₂, 37 SiO₂-ZrO₂ (*one-pot* hydrothermal) and 29 SiO₂-ZrO₂ (*Impregnation*).

The SiO₂-modified sample (**Figure 3-7**) prepared by the *one-pot* hydrothermal method (*e.g.* 37 SiO₂-ZrO₂ (H)) shows two peaks with chemical shifts of -83 ppm and -96 ppm, that represent a 2-fold (*Q*₂) and 3-fold (*Q*₃) coordination of Si-atoms as in Si(OSi)₂(OZr)₂ and Si(OSi)₃(OZr)₁ or Si(OSi)₂(OH)₂ and Si(OSi)₃(OH)₁, respectively.^{14, 30} Si-O-H and Si-O-Zr bonds are not distinguishable in ²⁹Si-NMR.^{22a} This allows us to conclude that SiO₂ and ZrO₂ exist in dispersed form in a mixed oxide. In contrast, the spectrum of the 29 SiO₂-ZrO₂ (Imp.) showed a broad signal at -114 ppm corresponding to *Q*₄, the 4-fold coordination of siloxane bonds Si(OSi)₄. This point to the fact that the SiO₂ phase and the ZrO₂ phase are partially segregated. Thus, it is concluded that SiO₂ forms a mixed oxide phase with ZrO₂ through a hydrothermal synthesis, whereas it is only deposited onto the ZrO₂ support by the impregnation method. With increasing SiO₂ concentration, these peaks are shifted towards lower field, due to the coordination of Si with Si increases (**Figure A 3-1**).

3.3.2 Hydrodeoxygenation of stearic acid

Scheme 3-2. Proposed reaction network for the hydrodeoxygenation of stearic acid, showing the decarbonylation route towards *n*-heptadecane (C₁₇), dehydration/hydrogenation to *n*-octadecane (C₁₈) and reversible esterification towards stearyl stearate.^{6b, 7, 32}

Catalytic hydrodeoxygenation of stearic acid was carried out on the Ni/SiO₂-SiO₂ catalysts. As shown in **Figure 3-8**, the initial conversion of stearic acid on Ni/37 SiO₂-ZrO₂ (H) resulted in 1-octadecanol as primary product, formed by the hydrogenation of the fatty acid (**Figure 3-9, B**).^{6a} Further conversion led to the appearance of secondary product, stearyl stearate ester, *n*-heptadecane (C₁₇) and *n*-octadecane (C₁₈). Stearyl stearate was formed through esterification of 1-octadecanol with stearic acid.^{6b, 31} This reaction is reversible and stearyl stearate reached a maximum at 8 h and decayed afterwards until depletion after 20 h. Only alkane products, *n*-heptadecane and *n*-octadecane, remained after 24 h. *n*-Heptadecane was formed *via* dehydrogenation of the 1-octadecanol intermediate to octadecanal with subsequent decarbonylation, and *n*-octadecane was formed *via* dehydration of 1-octadecanol to 1-octadecene with subsequent hydrogenation (**Scheme 3-2**).

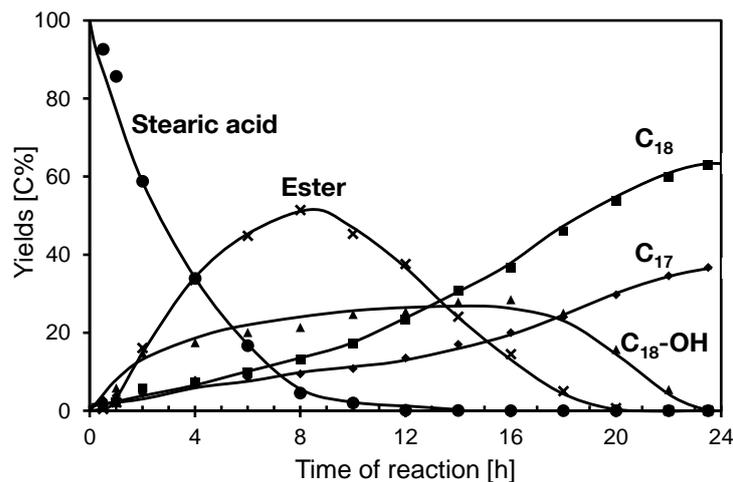

Figure 3-8. Product distribution for the hydrodeoxygenation of stearic acid over 10 wt% Ni/37 SiO₂-ZrO₂ (H) as a function of time, stearic acid (●), 1-octadecanol (▲), *n*-heptadecane (◆), *n*-octadecane (■) and stearyl stearate (×). Reaction conditions: stearic acid (0.5 g), 0.05 g 10 wt% Ni/37 SiO₂-ZrO₂ (H), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm, 8 h.

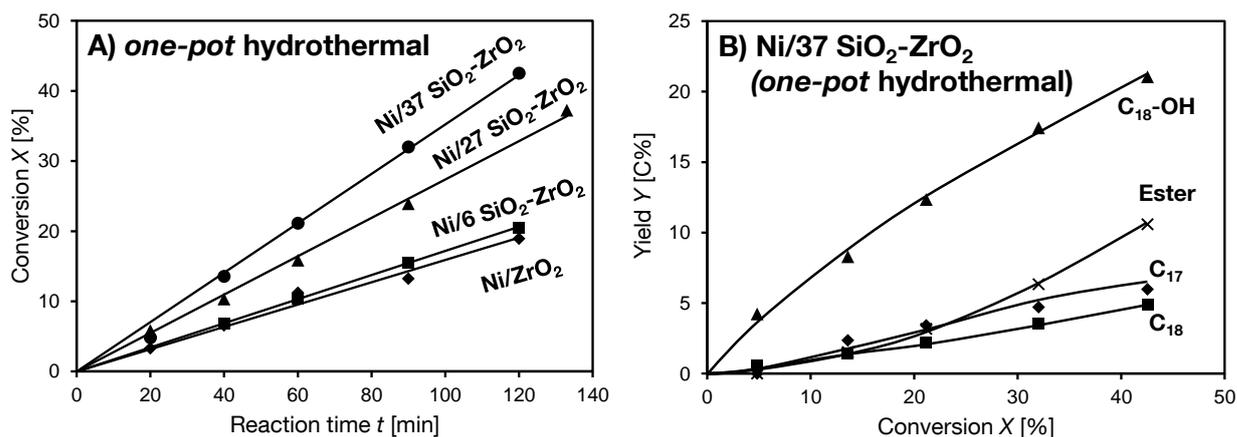

Figure 3-9. **A)** Conversion of stearic acid as a function of time. **B)** Yields of 1-octadecanol, stearyl stearate, *n*-heptadecane and *n*-octadecane over Ni/37 SiO₂-ZrO₂ (*one-pot hydrothermal*) as a function of stearic acid conversion. 1-octadecanol (▲), *n*-heptadecane (◆), *n*-octadecane (■) and stearyl stearate (×). Reaction conditions: stearic acid (0.5 g), Ni/SiO₂-ZrO₂ catalyst (10 wt% Ni, 0.05 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm, 2 h.

Figure 3-10 shows the Turnover frequency (TOF) of stearic acid and the concentration of BAS as a function of SiO₂-content for Ni/ZrO₂-SiO₂ (H) catalysts. Ni/ZrO₂ has a TOF of 64 (conversion rate of 3.2 mmol·g_{cat}⁻¹·h⁻¹). With increasing SiO₂-content, the TOF increased. The TOF of 297 (conversion rate of 8.6 mmol·g_{cat}⁻¹·h⁻¹) for Ni/37 SiO₂-ZrO₂ (H) was the highest TOF (**Figure 3-9, A** and **Figure 3-10**), decreasing with further increasing SiO₂ content (**Table A 3-3**). This trend is in line with the variation of BAS concentrations

and the specific surface area of the catalysts. The conversion rate of stearic acid on Ni follows approximately the concentration of BAS from the SiO₂-ZrO₂ support (**Figure 3-10**), indicating a promotion of hydrogenation activity of Ni by close BAS. Similar observations were made for hydrodeoxygenation of phenolic substrates by Song *et al.*¹¹ Because the conversion of stearic acid can be synergistically enhanced by ZrO₂,⁷ the markedly higher specific surface area may also contribute to the activity (**Figure A 3-2**). In contrast, hydrodeoxygenation of stearic acid over SiO₂-impregnated Ni/ZrO₂ catalysts showed a decrease of conversion rate with increasing SiO₂-content from 3.2 mmol·g_{cat}⁻¹·h⁻¹ for Ni/ZrO₂ to 1.4 mmol·g_{cat}⁻¹·h⁻¹ for Ni/29 SiO₂-ZrO₂ (Imp.) (**Figure A 3-3, A** and **Table A 3-4**). The products evolving with increasing stearic acid conversion is similar to that on Ni/ZrO₂. The decrease in activity is attributed to the SiO₂ partly covering ZrO₂, reducing so the accessible ZrO₂ surface.^{6a, 7}

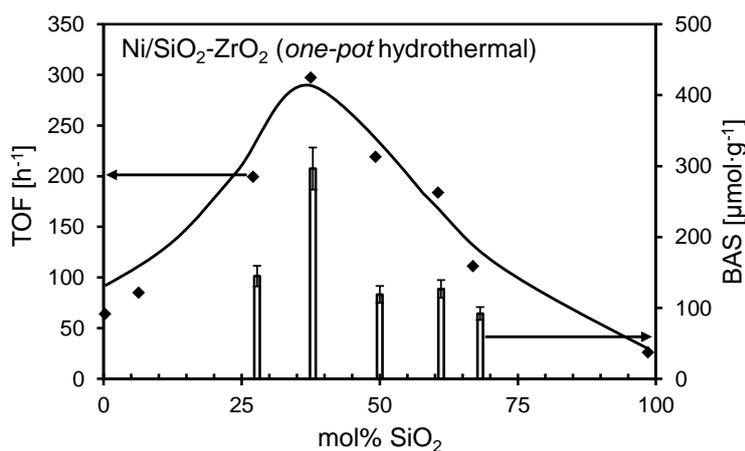

Figure 3-10. Turnover frequency (TOF) for the hydrodeoxygenation of stearic acid and concentration of Brønsted acid sites as a function of SiO₂-content in the Ni/SiO₂-ZrO₂ catalyst prepared by the hydrothermal method. Reaction conditions: stearic acid (0.5 g), Ni/SiO₂-ZrO₂ catalyst (10 wt% Ni, 0.05 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm, 2 h.

It is noticeable that on Ni/ZrO₂ catalyst, *n*-heptadecane was the dominant hydrocarbon product at full conversion and the *n*-octadecane yield was negligible,³² while on Ni/37 SiO₂-ZrO₂ (H), *n*-octadecane had a yield as high as 60%. Bare ZrO₂ only possesses LAS, whereas the presence of BAS in (H) catalysts enhanced the rate of 1-octadecanol dehydration, causing a shift in selectivity towards *n*-octadecane. This shift in product distribution from *n*-heptadecane to *n*-octadecane is advantageous from a carbon-economy point of view.^{6a, 33} In **Figure 3-11** the rate constants for the dehydration of 1-octadecanol leading to

C₁₈ and esterification of stearic acid with C₁₈-OH leading to stearyl stearate are shown. The rate constants for both reactions have a positive correlation with the BAS concentrations on the catalysts, indicating Brønsted acidic proton as the active site. Obviously, the conversion of stearic acid over Ni/37 SiO₂-ZrO₂ has the highest yield of *n*-octadecane, because it has the highest concentration of Brønsted acid sites.

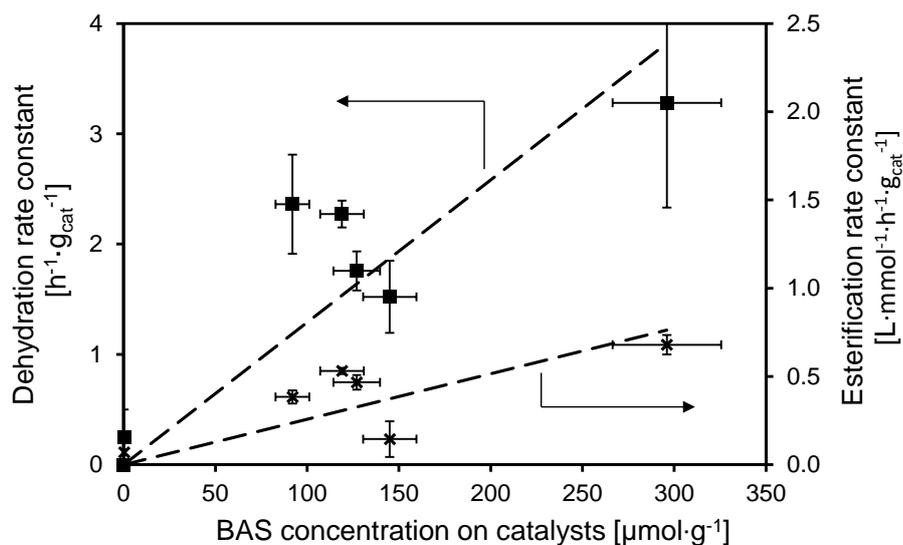

Figure 3-11. Rate constant for the dehydration of 1-octadecanol (■) and esterification of stearic acid and 1-octadecanol (×) normalized to catalyst weight as a function of concentration of BAS on Ni/SiO₂-ZrO₂ catalyst. Reaction conditions: stearic acid (0.5 g), Ni/SiO₂-ZrO₂ catalyst (10 wt% Ni, 0.05 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm, 2 h.

3.4 Conclusions

Hydrothermal synthesis of SiO₂-ZrO₂ mixed oxides led to materials with a maximum in Brønsted acid site concentration at approximately 40 mol% of SiO₂ and 60 mol% ZrO₂. Brønsted acid sites are concluded to be induced by the substitution in oxide lattices differing in the coordination of the cations, Si⁴⁺ and Zr⁴⁺. Differences in morphology resulted in high specific surface areas of these mixed oxides, having a spherical morphology with agglomerates of nano-layered materials. The higher concentration of Brønsted acid sites and higher specific surface area led to a maximum in the catalytic activity for stearic acid deoxygenation for Ni/37 SiO₂-ZrO₂. Remarkably, an increase in the rates of hydrogenation reactions by neighboring Brønsted acid sites and Ni particles was observed. While the high Brønsted acid

site concentration facilitates the dehydration of 1-octadecanol intermediate, which leads to an enhanced *n*-octadecane formation.

3.5 Experimental Section – Materials and Methods

3.5.1 Chemicals

All chemicals were purchased commercially: ZrO(NO₃)₂ × x H₂O (Sigma-Aldrich, 99%), urea (Sigma-Aldrich ACS reagent, 99.0-100.5%), LUDOX TM-40 (40 wt% SiO₂-suspension, Sigma-Aldrich), Ni(NO₃)₂·6 H₂O (Acros Organics, ≥98.5%), stearic acid (Sigma-Aldrich, ≥99.5% analytical standard), 1-octadecanol (Sigma-Aldrich, ≥99.5% Selectophore™), *n*-octadecane (Sigma-Aldrich, 99%), *n*-heptadecane (Sigma-Aldrich, 99%), dodecane (Sigma-Aldrich, ≥99%, *ReagentPlus*).

3.5.2 Catalyst preparation

Silica modified ZrO₂ supports with various SiO₂-content were prepared by two different methods (**Table 3-4**). For the first pathway, a hydrothermal synthesis route in the presence of ZrO₂ and a SiO₂ precursor was chosen. Various amount of LUDOX TM-40 (colloidal SiO₂-suspension), 44.4 g ZrO(NO₃)₂ · x H₂O and urea were dissolved in bi-distilled water according to **Table A 3-5 (Appendix, page 79)**. The solution was transferred to a stainless steel autoclave with a Teflon® liner. Herein, at 180 °C and autogenous pressure a precipitate was formed after 24 h. Therefore, this procedure is called *one-pot* hydrothermal method (H). After washing the precipitate with H₂O five times, it was dried overnight at 110 °C and then ground and calcined in synthetic air at 400 °C for 4 h at a heating rate of 2 °C·min⁻¹ (flow rate: 100 mL·min⁻¹). The labeling of both catalysts as well as supports corresponds to the mol% of SiO₂, derived from Si elemental analysis by ICP-OES.

Table 3-4: Overview of all SiO₂-ZrO₂ supports prepared by two different methods.

Catalyst ^a	mol%	mol%	mol%	mol%
	SiO ₂	Si	ZrO ₂	Zr
ZrO ₂	<1	<1	100	33
6 SiO ₂ -ZrO ₂ (H)	6	2.1	94	31
27 SiO ₂ -ZrO ₂ (H)	27	9.0	73	24
37 SiO ₂ -ZrO ₂ (H)	37	13	63	21
49 SiO ₂ -ZrO ₂ (H)	49	16	51	17
61 SiO ₂ -ZrO ₂ (H)	61	20	39	13
67 SiO ₂ -ZrO ₂ (H)	67	22	33	11
SiO ₂	99	33	<1	<1
4 SiO ₂ -ZrO ₂ (Imp.)	4	1.4	96	32
16 SiO ₂ -ZrO ₂ (Imp.)	16	5.5	83	28
29 SiO ₂ -ZrO ₂ (Imp.)	29	9.7	71	24

[a] Number in the label is mol% SiO₂. (H) ≡ *one-pot* hydrothermal synthesis method; (Imp.) ≡ Impregnation method

For the second route, *monoclinic* ZrO₂ was impregnated with LUDOX TM-40 to prepare a mixed oxide enriched at the surface with SiO₂. For this, *monoclinic* ZrO₂ was prepared as shown previously ^{12a, 32} and LUDOX was added dropwise onto the powdered ZrO₂ with various amounts as shown in **Table A 3-6**. Subsequently, the SiO₂ *impregnated* ZrO₂ was suspended with water, stirred for 3 h at ambient temperature and dried overnight at 110 °C. This is called impregnation method (Imp.).

The 10 wt% supported Ni catalysts were prepared by the wet impregnation technique. The Ni metal precursor, Ni(NO₃)₂·6 H₂O (3.30 g), was dissolved in deionized H₂O, and the resultant solution was added dropwise into 6.0 g of the powdered support with stirring in ambient air. The slurry was further stirred for 4 h, followed by drying at 110 °C overnight. Subsequently, the ground solid was calcined in synthetic air (flow rate: 100 mL·min⁻¹) at 450 °C for 4 h (heating rate: 4 °C·min⁻¹) and reduced in H₂ flow (flow rate: 100 mL·min⁻¹) at 500 °C for 4 h (heating rate: 4 °C·min⁻¹).

3.5.3 Catalyst characterization

X-Ray powder diffraction (XRD) was performed on a Philips X'Pert Pro System equipped with a Cu K α radiation source (40 kV/45 mA) with 1.08° min⁻¹ in the 2 θ range of 5–70°. The crystal size of ZrO₂ was determined *via* Scherrer equation from full width at half maximum of the (111) diffraction peak of ZrO₂.³⁴

N₂-sorption. The BET surface area was determined by adsorption-desorption with N₂ at -196 °C using the Sorptomatic 1990 series instrument. The sample was activated in vacuum at 250 °C for 2 h before measurement. In order to measure **H₂-chemisorption** in Thermo Scientific's Surfer instrument, the Ni based catalysts were reduced in H₂-flow at 450 °C for 1 h and then evacuated at 300 °C for 1 h. The H₂ adsorption isotherms accounting for both chemisorption and physisorption were measured at a pressure ranging from 9 to 400 mbar at 25 °C. Afterwards, the system was evacuated for 20 min to remove physisorbed H₂ and to obtain chemisorbed H₂ after subtraction. The concentration of chemisorbed hydrogen on the metal was determined by extrapolating the isotherm to zero H₂ pressure. The Ni dispersion was deduced by assuming an average surface Ni to H ratio of 1.

Temperature programmed desorption (TPD) of ammonia and carbon dioxide was carried out in a 6-fold parallel reactor system. The pressed samples (500-710 μ m) were first activated in He at 500 °C for 1 h and loaded with the adsorbent NH₃ or CO₂ at a partial pressure of 1 mbar and 100 °C or 40 °C, respectively. The samples were then purged with He for 1 h in order to remove physisorbed species. After activation, the six samples were heated from 100-770 °C with a rate of 10 °C·min⁻¹ to desorb NH₃ and from 40 to 700 °C to remove CO₂, and the signals were detected by a Balzers QME 200 mass spectrometer.

Atomic absorption spectroscopy (AAS) was used to determine the Ni content of the catalysts with a UNICAM 939 AA-Spectrometer. Prior to Ni determination, the catalysts were dissolved in boiling concentrated sulfuric acid. Si-content of the supports was obtained by **Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES)** using a HORIBA Jobin Yvon Ultima II spectrometer. In order to prepare the sample for measurement, the finely ground powder was digested in Merck's Spectromelt A14 (Li₂B₄O₇, LiBO₂).

High Resolution Scanning Electron Microscopy (HR-SEM) of the SiO₂ modified supports was performed with a JOEL JSM-7500F SEM. The finely ground samples were

mounted on a multi-sample-holder by standard preparation technique and measured with a secondary electron ionization detector (SEI).

IR spectroscopy of adsorbed pyridine (py-IR) was performed on a Thermo Fisher Nicolet 5700 IR spectrometer at a resolution of 4 cm⁻¹ with 120 scans in the range of 1000-4000 cm⁻¹ equipped with CaF₂ windows. For the adsorption measurements, the samples of ZrO₂ with various content of SiO₂ were pressed into a self-supporting disc (wafer) and mounted on the sample holder. The samples were activated under vacuum ($p = 10^{-6}$ mbar) at 450 °C for 1 h (heating ramp: 10 K·min⁻¹). As soon as the sample cooled to 150 °C, a spectrum of the activated sample was taken. Subsequently, adsorption of pyridine was performed at 0.1 mbar for 30 min until saturation/equilibration of the surface was reached and the peak area of the IR signal remained constant. After physisorbed pyridine was removed by evacuation ($p = 10^{-6}$ mbar) at 150 °C, another spectrum was recorded. Finally, a spectrum was taken after desorption at 450 °C for 30 min ($p = 10^{-6}$ mbar). The IR spectra of adsorbed pyridine were obtained by subtracting the spectrum of the activated sample, and then were normalized by the weight of the sample wafer. For quantification, the spectra were analyzed according to the procedure described earlier, using molar integral extinction coefficients of 0.73 cm·μmol⁻¹ (BAS) and 0.96 cm·μmol⁻¹ (LAS).³⁵

Solid state ²⁹Si MAS NMR spectroscopy measurements (²⁹Si-NMR) of SiO₂-ZrO₂ samples were obtained using a Bruker Advance 300 MHz multinuclear FT spectrometer ($B = 7.05$ T) at the corresponding ²⁹Si resonance frequency of 59.6 MHz. The powdered samples were fully hydrated before packing them into a 4 mm ZrO₂ pencil type rotor. Spinning at a speed of 10 kHz, 7000-8000 scans were recorded using a single-pulse technique with a pulse length of 6 μs and a repetition time of 10 s. The external standard Si[Si(CH₃)₃]₄ with a chemical shift of 9.8 ppm for ²⁹Si (*versus* TMS) was used.

3.5.4 Measurement of the catalytic activity

In order to test the described catalyst systems, stearic acid (0.5 g) and the corresponding catalyst (0.05 g) were first loaded into the autoclave reactor (Parr, 300 mL) with dodecane (100 mL), and then purged three times with H₂. The reaction was carried out at 260 °C under 40 bar of H₂ for 2 h at a stirring speed of 600 rpm. *In situ* samples were drawn after 20, 40, 60, 90 and 120 min, and were analyzed by Agilent 7890B GC system, equipped

with a flame ionization detector (FID) and Agilent 5977 MS detector, using a HP-5 capillary column (30 m, 0.32 mm inner diameter, 0.25 μm film). Reproducibility of the rates was better than ±5% for all experiments.

Conversion = (weight of converted reactant / weight of the starting reactant) × 100%.
Yield (C%) = (C atoms in each product / C atoms in the starting reactant) × 100%. Selectivity (C%) = (C atoms in each product/sum of C atoms in all the products) × 100%. Turnover frequency (TOF) is the reaction rate normalized by accessible surface Ni atoms, which were determined by chemisorption of hydrogen or concentration of BAS, which was determined by *py*-IR (where applicable). TOF = mole of converted reactant / mole of accessible Ni on the catalyst's surface or mole of converted reactant / concentration of BAS. Rate of dehydration = Δ yield of C₁₈ / Δ time). Rate constant of dehydration = rate of dehydration / concentration of 1-octadecanol.

3.6 Acknowledgements

Financial support in the framework of AlgenFlugKraft (FKZ LaBay74) project, supported by Bavarian Ministry of Economic Affairs and Media, Energy and Technology (“Bayerisches Staatsministerium für Wirtschaft und Medien, Energie und Technologie”) and Bavarian State Ministry of Education, Science and the Arts (“Bayerisches Staatsministerium für Bildung und Kultus, Wissenschaft und Kunst”) is highly appreciated. I thank Franz-Xaver Hecht for N₂-sorption and H₂-Chemisorption, Martin Neukamm for AAS measurements, Tommy Hofmann, Thomas Gronauer and Julia Tšeglakova for the catalyst synthesis. The fruitful discussions with Dipl.-Min. Katia Rodewald, Dr. Gabriele Raudaschl-Sieber and Dr.-Ing. Christian A. Gärtner are highly appreciated. Johannes A. Lercher acknowledges support for his contribution by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences & Biosciences for exploring alternative oxidic supports for deoxygenation reactions.

3.7 Contributions

Sebastian Foraita planned the experiments, synthesized the catalysts, carried out the reactions, characterized the materials, analyzed the results and wrote the manuscript. Yue

Liu, Gary L. Haller and Eszter Baráth helped discussing the results and correcting the manuscript. Chen Zhao supported the work in the initial stage (planning and discussions). As the general supervisor, Johannes A. Lercher contributed in discussing the results, planning further steps and correcting the manuscript.

Chapter 4

Hydrodeoxygenation of Stearic Acid on bimetallic $\text{Ni}_x\text{Cu}_{1-x}/\text{ZrO}_2$

A manuscript with the content of the following chapter will be submitted to *ChemCatChem* for publication. Contributions from colleagues in addition to the author of this thesis are stated at the end of this chapter (page 103).

The physical or chemical mixture of Ni and Cu metal supported on ZrO_2 led to catalysts converting stearic acid to long chain alkanes more efficiently than monometallic Ni/ZrO_2 .

Keywords: Hydrodeoxygenation • Bimetallic Catalysts • Alloy • Ni Cu • ZrO_2 • Stearic acid

4.1 Abstract

Hydrodeoxygenation of stearic acid to n -heptadecane on Ni/ZrO_2 proceeds via hydrodeoxygenation of stearic acid to octadecanal with subsequent decarbonylation of the aldehyde to n -heptadecane. The addition of Cu to Ni/ZrO_2 enhanced the total reaction rate.

This effect is seen for a physical mixture with Cu/ZrO₂ and for the ZrO₂ supported Ni_xCu_{1-x} alloy. Cu/ZrO₂ was significantly more active for the hydrodeoxygenation of stearic acid to 1-octadecanol than Ni/ZrO₂. Decarbonylation of octadecanal that is in equilibrium with 1-octadecanol proceeded, however, with a much higher rate on Ni/ZrO₂ or Ni_xCu_{1-x}/ZrO₂. The combination of the higher hydrodeoxygenation of the acid to the aldehyde or alcohol and the high rate of elimination of water on Ni or Ni_xCu_{1-x} lead to the superior properties of the new catalyst.

4.2 Introduction

Microalgae are envisioned as the optimal raw material for producing third generation biofuels, because they are rich in lipids, provide rapid growth rates and are independent of arable land.¹ In order to obtain molecules in the diesel and kerosene range, the triglycerides need to be cleaved and deoxygenated. The commercial applicability of hydrotreating vegetable oils has been demonstrated by the NExBTL process (Neste Oil, Porvoo, 340 kt·a⁻¹) utilizing sulfide NiMo/Al₂O₃ catalysts.² Although such a process can use the existing infrastructure, the sulfide catalysts are disadvantageous for the conversion of triglyceride feedstocks that are virtually free of sulfur, because leaching of the sulfide catalysts leads to deactivation of the catalyst and contamination of the product stream.³ Supported noble metals such as Ru, Pd and Pt catalysts offer high activity and selectivity for hydrodeoxygenation of triglycerides and fatty acids without catalyst leaching, but the use of such catalysts is economically challenging due to the high cost of such precious metals.⁴ Other catalysts reported have been based on tungsten carbide. However, their activity was significantly lower than that of commercial hydrotreating catalysts (NiMo/Al₂O₃).⁵

Therefore, two types of novel sulfur-free Ni based catalysts were developed in order to directly convert microalgae oil quantitatively to diesel-range hydrocarbons at 260 °C and 40 bar H₂.⁶ After fast hydrogenolysis of microalgae oil (triglycerides) into propane and fatty acids, the latter are hydrodeoxygenated into alkanes.^{6a}

Stearic acid is one of the most abundant fatty acids in a representative microalgae oil and therefore used as a model compound.^{6b} Its reductive conversion on Ni/ZrO₂ occurs *via* two redundant pathways – either by Ni alone or synergistically enhanced by Ni and the ZrO₂ support. On Ni, stearic acid is reduced to the alkane by hydrodeoxygenation and subsequent

decarbonylation *via* the aldehyde. Oxygen defect sites of ZrO₂ enable the combined adsorption and deoxygenation of fatty acid and the abstraction of α -H, leading to the formation of a ketene intermediate and the elimination of H₂O.⁷ This ketene is in turn hydrogenated to aldehyde on Ni and subsequently decarbonylated to the corresponding alkane and CO.⁸ Consequently, both routes lead to an alkane with one carbon less than the fatty acid, *i.e.* *n*-heptadecane (C₁₇) from stearic acid (C₁₈).

Two problems are prominent with Ni based catalysts. Their intrinsic rate for hydrogen addition reactions to oxygenates is significantly lower than those of noble metals and, moreover, Ni tends to form relatively large metal particles, further reducing the overall catalytic activity.^{3a} Therefore, the focus of this research included Cu, as a catalyst component, that is well-known to catalyze hydrodeoxygenation of fatty acids to alcohols (*e.g.*, Adkins catalyst)⁹ and which also helps keeping the base metal catalysts dispersed.¹⁰ Thus, the impact of Cu on the Ni/ZrO₂ based catalysts is explored in this chapter, showing that both the fraction of exposed metal as well as the electronic properties were favorably modified to enhance the rates of hydrodeoxygenation and decarbonylation.

4.3 Results and Discussion

4.3.1 Catalyst characterization

Physicochemical properties

Five catalysts with different Ni_xCu_{1-x}-ratios were prepared, ranging from ZrO₂ supported pure Ni to pure Cu catalysts. The labeling denotes the atomic fraction of the two elements. The overall concentration of Ni and Cu is compiled in **Table 4-1**. N₂ physisorption showed the specific surface area of all catalysts to be $(84 \pm 3) \text{ m}^2 \cdot \text{g}^{-1}$. The varying Ni_xCu_{1-x}-concentrations did not influence the overall specific surface area. However, as the Cu and Ni fractions increased from 0.21:0.79 to 0.71:0.29, the dispersion of Ni increased from 1.5 to 2.8% and the particle size of Ni decreased from 68 to 36 nm (except Ni/ZrO₂) as calculated from H₂-chemisorption¹¹ and determined from the line broadening of the Ni peaks in the X-ray diffractogram (XRD).¹² The acid-base-properties of the catalysts did not change across all catalysts. The acidity was $0.19 \pm 0.04 \text{ mmol} \cdot \text{g}^{-1}$, the basicity $0.27 \pm 0.02 \text{ mmol} \cdot \text{g}^{-1}$, both originating from the ZrO₂ support.¹³ From the constant BET surface area, concentration of acid-base-sites and diffraction pattern it is concluded that the support was not modified by

the present preparation method and subtle variations did not influence the kinetic measurements.

Table 4-1: Physicochemical properties of bimetallic Ni_xCu_{1-x}/ZrO₂ catalysts.

Catalyst ^a	S_{BET}	wt% Ni ^b	wt% Cu ^b	$d_{\text{Ni(111)}}^{\text{c}}$	$d_{\text{Cu(111)}}^{\text{c}}$	D_{Ni}^{d}	d_{Ni}^{d}	Conc. of acid sites ^e	Conc. of basic sites ^f
	[m ² ·g ⁻¹]	[%]	[%]	[nm]	[nm]	[%]	[nm]	[mmol·g ⁻¹]	[mmol·g ⁻¹]
Ni/ZrO ₂	82	10	0	20	-	3.5	29	0.19	0.28
Ni _{0.79} Cu _{0.21} /ZrO ₂	81	7.5	2.1	10	-	1.5	68	0.23	0.27
Ni _{0.59} Cu _{0.41} /ZrO ₂	87	5.6	4.2	-	-	1.8	55	0.23	0.27
Ni _{0.29} Cu _{0.71} /ZrO ₂	83	2.5	6.5	-	85	2.8	36	0.16	0.25
Cu/ZrO ₂	85	0	8.7	-	> 100	-	-	0.15	0.29

[a] Label according to molar ratio of Cu-Ni. [b] Determined by AAS. [c] Calculated from XRD by Scherrer equation. [d] Dispersion (D) and particle size (d) were determined by H₂-Chemisorption. [e] Determined by TPD of NH₃. [f] Determined by TPD of CO₂.

Monoclinic ZrO₂ was detected by X-ray powder diffractogram (XRD) *via* the corresponding peaks at 24.5, 28.3, 31.6, 34.5°, 35.3° and 40.7° (JCPDS card No. 37-1484)¹⁴ (**Figure 4-1**). A small shoulder at 30.2° is assigned to *tetragonal* ZrO₂ (JCPDS card No. 17-0923),¹⁵ but it was only present in very low concentrations. Most diffractograms showed the distinctive peaks of Ni(111) at 44.6° and Ni(200) at 51.9° corresponding to Ni⁰ (JCPDS 04-0850)¹⁶ primarily for Ni/ZrO₂.

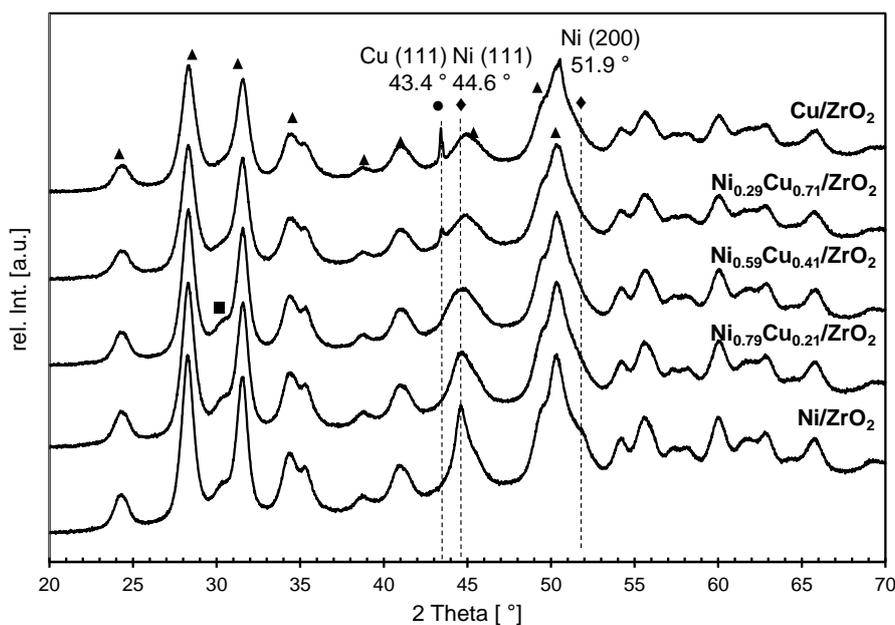

Figure 4-1. XRD patterns of Ni_xCu_{1-x}/ZrO₂ ($x = 1, 0.79, 0.59, 0.29, 0$) in the 2θ range of 20-70°. Monoclinic ZrO₂ (▲), tetragonal ZrO₂ (■).

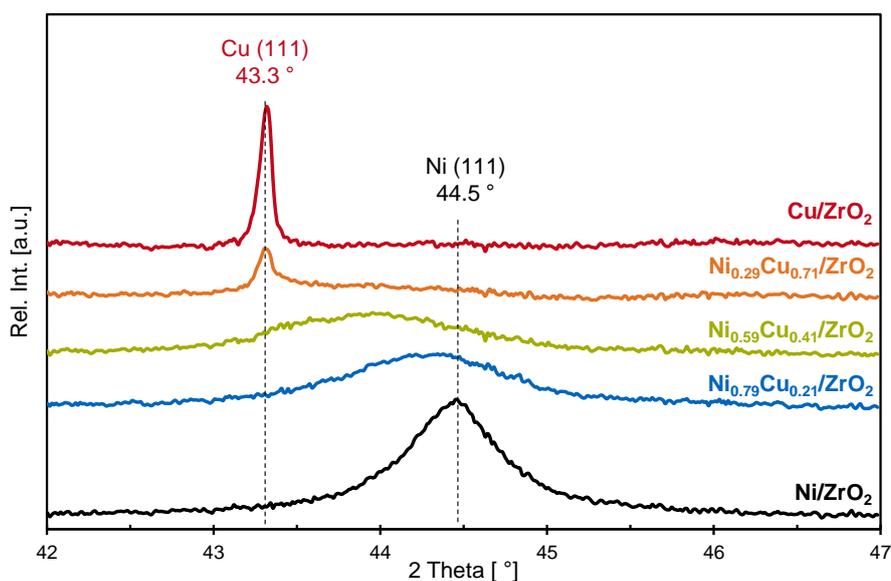

Figure 4-2. XRD patterns of Ni_xCu_{1-x}/ZrO₂ ($x = 1, 0.79, 0.59, 0.29, 0$) catalysts by subtraction of the support *m*-ZrO₂ in the 2θ range 42-47°.

In contrast, a signal of Cu(111) at 43.4° was only observed for Cu/ZrO₂ and Ni_{0.29}Cu_{0.71}/ZrO₂ (JCPDS 04-0836).¹⁶ The Cu(200) peak at 50.6° overlaps with ZrO₂(220) at 50.1°.^{15a, 17} It should be noted that the particle size of Cu in Cu/ZrO₂ is beyond the limitation of the Scherrer equation.¹⁸ Between the peak of Cu(111) at 43.4° and Ni(111) 44.6° a broad signal appeared, attributed to the presence of a Ni_xCu_{1-x}-alloy.¹⁶ This broad reflection is

more visible, after subtraction of the *m*-ZrO₂ pattern (**Figure 4-2**), a peak broadening for increasing Cu content is overserved, which can be assigned to a decrease of the particle size of the alloy.

Figure 4-3 shows the IR spectra of adsorbed CO on various Ni_xCu_{1-x}/ZrO₂ catalysts at 40 °C and $p(\text{CO}) = 0.3 \text{ mbar}$. For monometallic Ni/ZrO₂, the band at 2038 cm⁻¹ is attributed to linearly bound CO on Ni⁰ (CO-Ni).¹⁹ For the bimetallic Ni_xCu_{1-x}/ZrO₂ catalysts, the band of CO-Ni decreased to 2019, 2011 and 2004 cm⁻¹ with increasing concentrations of Cu. This gradual downward shift indicates an increase in the electron density at the Ni surface atoms.^{11, 20} Using rigid band to approximate the changes, it is hypothesized that electrons from the fully occupied d-band (4s¹ 3d¹⁰) of Cu are donated to the partially unoccupied d-band (4s² 3d⁸) of Ni.^{20a} Bridged carbonyls (b-CO-Ni) are visible at 1921 cm⁻¹ as a distinct peak for Ni/ZrO₂ and a small peak or shoulder for the Ni_xCu_{1-x}/ZrO₂ materials. Cu/ZrO₂ only shows minor adsorption of CO, which led to a band at 2100 cm⁻¹.¹¹

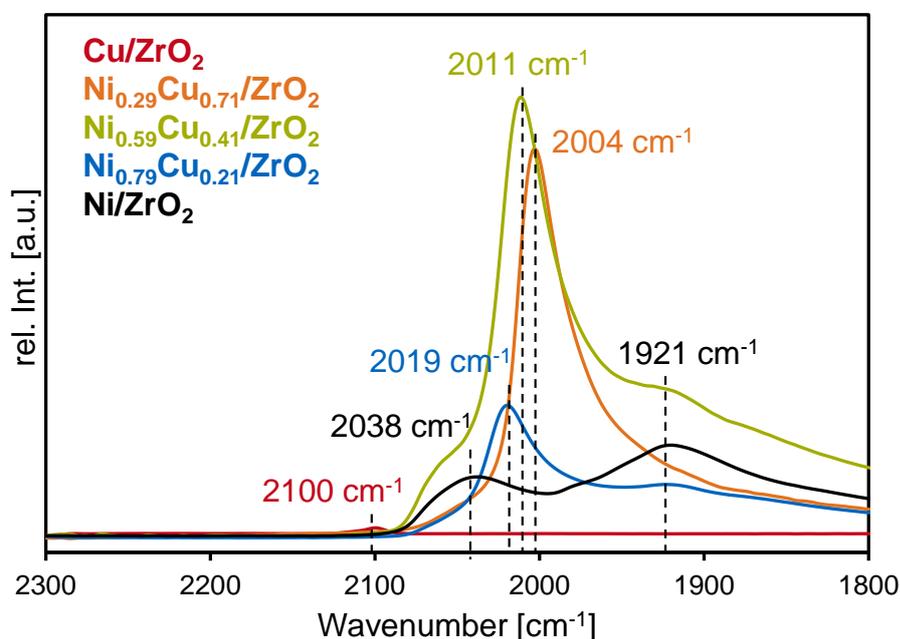

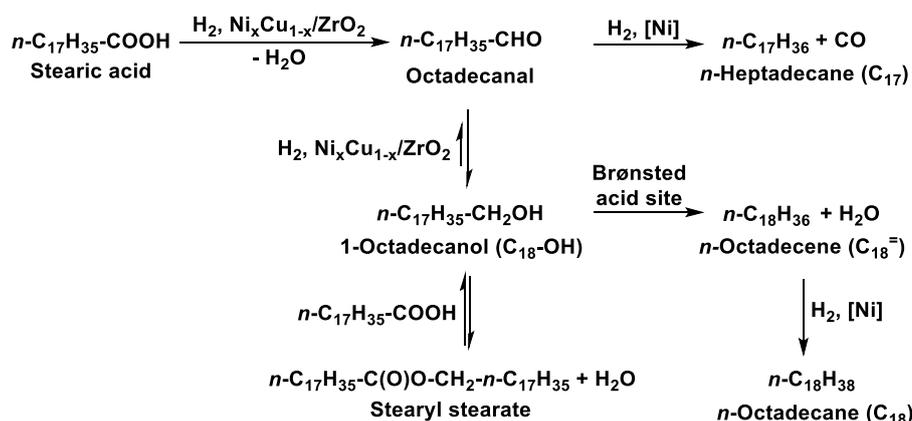

Figure 4-3. IR spectra of CO (0.3 mbar) adsorbed at 40 °C on Ni_xCu_{1-x}/ZrO₂ ($x = 1, 0.79, 0.59, 0.29, 0$).

4.3.2 Kinetic measurements and product distribution

Proposed reaction network for hydrodeoxygenation of stearic acid is shown in **Scheme 4-1**. The first step of the HDO reaction sequence is the hydrodeoxygenation of the stearic acid to octadecanal followed by a reversible hydrogenation to 1-octadecanol. This step is catalyzed by each of Ni, Cu or ZrO₂ with varying rates. In the subsequent step, octadecanal is decarbonylated to *n*-heptadecane. This reaction occurs only on Ni. Catalyzed by Brønsted acid sites, water is eliminated from 1-octadecanol forming *n*-octadecene, which is further hydrogenated to *n*-octadecane. It should be pointed out that additionally 1-octadecanol and stearic acid reversibly form stearyl stearate, which is consumed during the reaction.^{6b, 7-8}

Scheme 4-1. Proposed reaction network for the hydrodeoxygenation of stearic acid.^{6b, 7-8}

The reaction network presented in **Scheme 4-1** consists of two key pathways, which require in-depth analysis, (i) the hydrodeoxygenation to 1-octadecanol *via* octadecanal and (ii) the decarbonylation of octadecanal. As presented previously, the hydrodeoxygenation of stearic acid to the aldehyde is the rate determining step on Ni/ZrO₂ (**Scheme 4-1**).^{6a} Since this reaction step can be catalyzed by all catalyst components, adjustments of the individual rates to hydrodeoxygenation are critical in order to achieve higher activity.

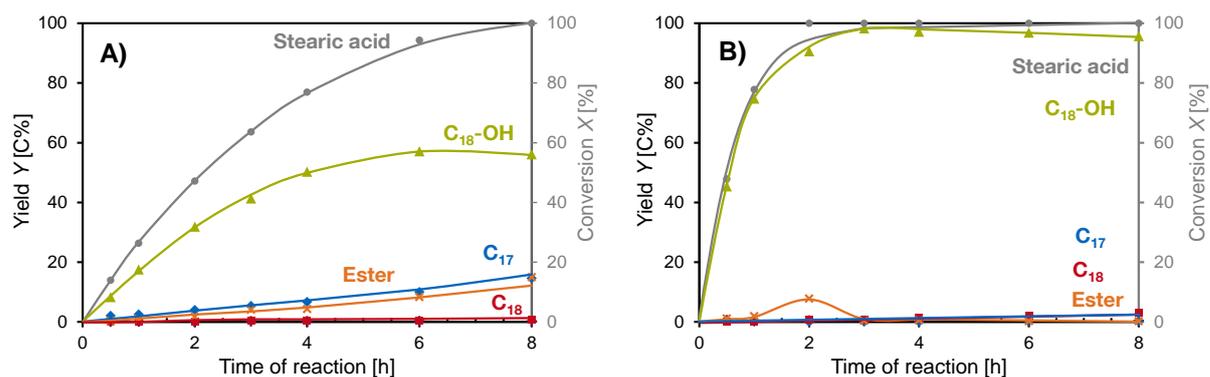

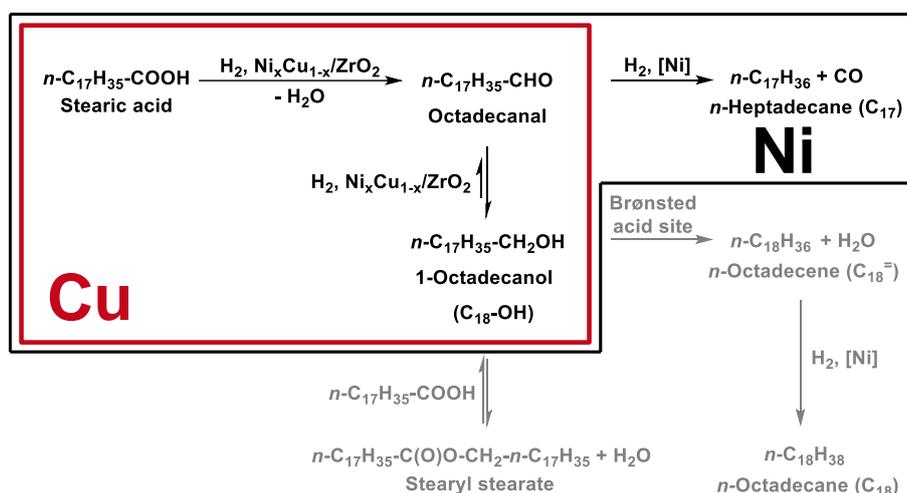

Figure 4-4. Product distribution for the hydrodeoxygenation of stearic acid over Ni/ZrO₂ (A) and Cu/ZrO₂ (B) as a function of time, conversion of stearic acid (●), yield of 1-octadecanol (▲), *n*-heptadecane (◆), *n*-octadecane (■), octadecanal (+) and stearyl stearate (×). Reaction conditions: Stearic acid (0.5 g), Ni/ZrO₂ or Cu/ZrO₂ (0.2 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm.

Scheme 4-2. Schematic representation of the hydrodeoxygenation sequence of stearic acid on Ni/ZrO₂ and Cu/ZrO₂.

In **Figure 4-4** the full conversion of stearic acid over Ni/ZrO₂ and Cu/ZrO₂ are compared as a function of time. On both catalysts, hydrodeoxygenation of stearic acid to 1-octadecanol *via* octadecanal appears as a primary reaction, and the formation rates of alkanes including *n*-heptadecane and small amount *n*-octadecane were secondary reactions. Stearyl stearate is concluded to be caused by the reversible esterification between 1-octadecanol and stearic acid and only occurring on Ni/ZrO₂. Despite the fast consumption of stearic acid on Cu/ZrO₂, 1-octadecanol was hardly converted further, in line with earlier observations by Ponec.²¹ Thus the formation of hydrocarbons were very slow. In contrast, Ni/ZrO₂ catalysts showed a faster formation of hydrocarbons even though the conversion of stearic acid was

slower.^{6a, 7} This observation clearly indicates that Cu is active in the hydrodeoxygenation of the carboxylic acid, but not in the decarbonylation of the aldehyde formed (Scheme 4-2).

Stearic acid hydrodeoxygenation

In order to enhance the overall conversion rate of stearic acid, physical mixtures of monometallic Ni/ZrO_2 and Cu/ZrO_2 were used as catalysts. With increasing content of Cu/ZrO_2 in the mixture, the reaction rate increased linearly (Figure 4-5). The slope in the yield of 1-octadecanol versus the conversion of stearic acid is only slightly lower than one for all five materials, indicating a very selective conversion (Figure 4-6).

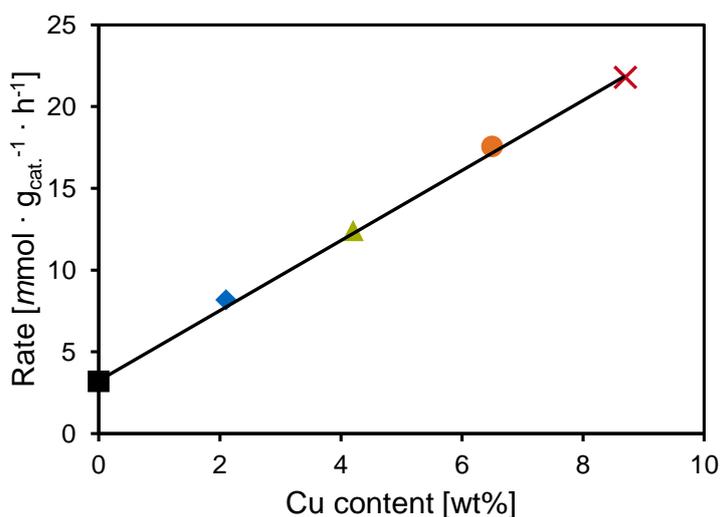

Figure 4-5. Initial reaction rate for the hydrodeoxygenation of stearic acid over physical mixtures of monometallic Ni/ZrO_2 and Cu/ZrO_2 as a function of Cu content. Reaction conditions: Stearic acid (0.5 g), $x \text{ Ni}/\text{ZrO}_2 + (1-x) \text{ Cu}/\text{ZrO}_2$ catalyst ($x = 1, 0.79, 0.59, 0.29, 0$, sum 0.05 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm. Cu/ZrO_2 (×), 0.29 $\text{Ni}/\text{ZrO}_2 + 0.71 \text{ Cu}/\text{ZrO}_2$ (●), 0.59 $\text{Ni}/\text{ZrO}_2 + 0.41 \text{ Cu}/\text{ZrO}_2$ (▲), 0.79 $\text{Ni}/\text{ZrO}_2 + 0.21 \text{ Cu}/\text{ZrO}_2$ (◆), Ni/ZrO_2 (■).

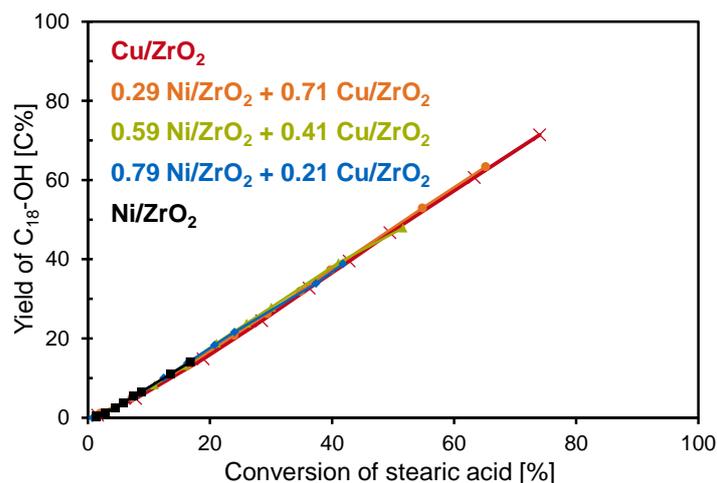

Figure 4-6. Yield of 1-octadecanol as function of stearic acid conversion over physical mixtures of monometallic Ni/ZrO₂ and Cu/ZrO₂. Reaction conditions: Stearic acid (0.5 g), Stearic acid (0.5 g), x Ni/ZrO₂ + (1- x) Cu/ZrO₂ catalyst ($x = 1, 0.79, 0.59, 0.29, 0$, sum 0.05 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm.

In addition, co-impregnated Ni_xCu_{1-x}/ZrO₂ led to identical reaction rates (Figure A 4-1, Appendix, page 104) than for the physical mixtures (Figure 4-5). Thus, it is concluded that the alloy formation does not enhance the rate of hydrodeoxygenation.

Decarbonylation of 1-octadecanol

Under typical reaction conditions ($p(\text{H}_2) = 40$ bar), mainly 1-octadecanol is present and the concentration of octadecanal is low at equilibrium concentration.^{6a} Thus, to explore the decarbonylation 1-octadecanol was used as starting material. The respective turn over frequencies (TOF) are given in Figure 4-7. On Cu/ZrO₂, 1-octadecanol was not converted to *n*-heptadecane. In general, the physically mixed Ni/ZrO₂ + Cu/ZrO₂ catalysts had a slightly higher TOF than Ni/ZrO₂. The similar TOFs for the three physical mixtures demonstrate the absence of a promoting effect on the Ni sites by the physical mixture. In contrast, all co-impregnated Ni_xCu_{1-x}/ZrO₂ catalysts had higher TOF ($> 440 \text{ mol}_{\text{C}_{18}\text{-OH}} \cdot \text{mol}_{\text{Ni}}^{-1} \cdot \text{h}^{-1}$) than the physically mixed equivalents ($< 125 \text{ mol}_{\text{C}_{18}\text{-OH}} \cdot \text{mol}_{\text{Ni}}^{-1} \cdot \text{h}^{-1}$). This higher activity is attributed to the higher electron density on Ni in Ni_xCu_{1-x}. In line with the lower wave number of adsorbed CO with increasing Cu concentration, the TOFs increased gradually in parallel.

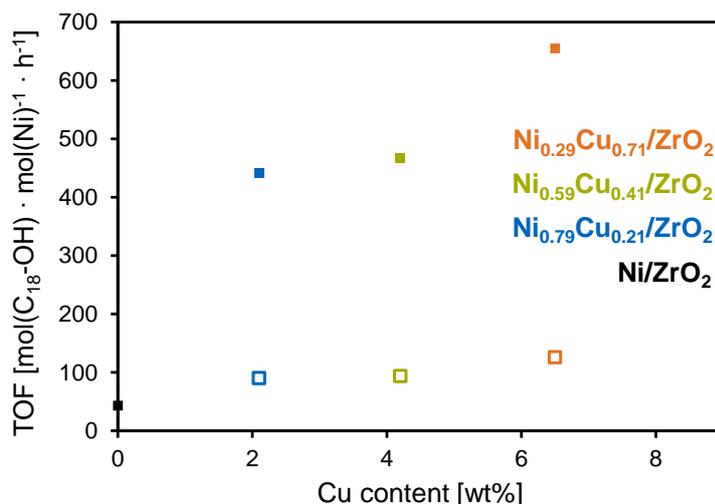

Figure 4-7. Turn over frequency converting 1-octadecanol as a function of Cu content. Reaction conditions: 1-octadecanol (0.5 g), x Ni/ZrO₂ + (1- x) Cu/ZrO₂ (□) or Ni _{x} Cu_{1- x} /ZrO₂ (■), $x = 1, 0.79, 0.59, 0.29$ (sum 0.05 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm.

Full conversion experiments with stearic acid

The first reaction step (hydrodeoxygenation of the carboxylic acid) occurred mainly on Cu. The second reaction step (decarbonylation of 1-octadecanol) was not catalyzed by Cu (**Figure 4-4**). The yield of 1-octadecanol as a function of reaction time is given for the physical mixtures x Ni/ZrO₂ and (1- x) Cu/ZrO₂ catalyst ($x = 1, 0.79, 0.59, 0.29, 0$) in **Figure 4-8, A** and for co-impregnated catalysts Ni _{x} Cu_{1- x} /ZrO₂ ($x = 1, 0.79, 0.59, 0.29, 0$) in **Figure 4-9, A**. Note that the rate for hydrodeoxygenation of stearic acid is the same for physical mixtures and respective Ni _{x} Cu_{1- x} /ZrO₂ catalysts (**Figure A 4-1**). The decarbonylation is more sensitive to the Nickel content and the alloy formation (**Figure 4-7**). Consequently, the same formation rate of 1-octadecanol is seen in **Figure 4-8, A** and **Figure 4-9, A**, but a more rapid consumption of the intermediately formed 1-octadecanol on Ni _{x} Cu_{1- x} /ZrO₂ than on respective physical mixtures. Within the physical mixtures, 0.29 Ni/ZrO₂ + 0.71 Cu/ZrO₂ gave the highest yield of 1-octadecanol after eight hours and consequently the lowest yield of *n*-heptadecane (**Figure 4-8, B**). For the other two mixtures with a higher content of Ni, 1-octadecanol is formed comparably fast, but consumed more rapidly in line with a higher rate of *n*-heptadecane formation. Additionally, the obtained yields of *n*-heptadecane are higher than over pure Ni/ZrO₂,^{6a, 7-8} which emphasizes the benefit of Cu/ZrO₂ as a co-catalyst for the conversion of stearic acid to *n*-heptadecane.

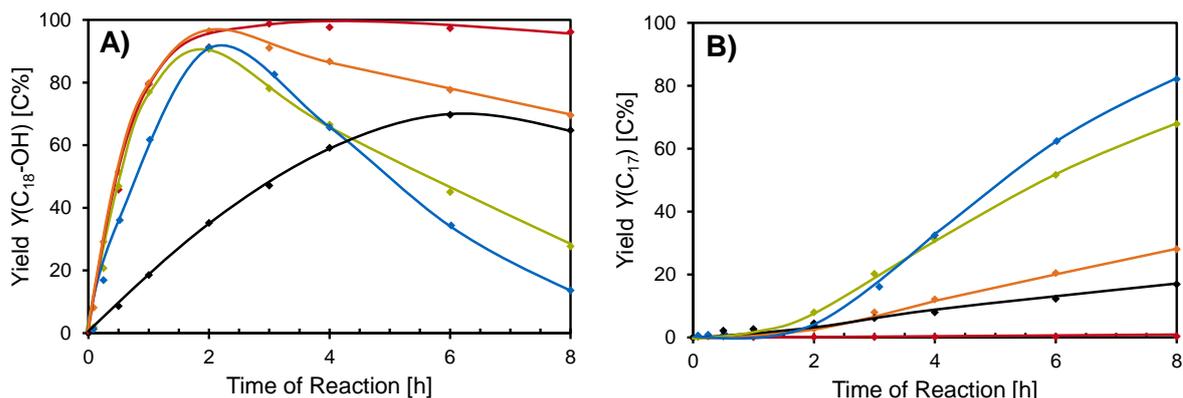

Figure 4-8. Yield of 1-octadecanol (A) and yield of *n*-heptadecane (B) as function of time over physical mixtures of monometallic Ni/ZrO₂ and Cu/ZrO₂ (molar ratio Cu:Ni). Reaction conditions: Stearic acid (0.5 g), *x* Ni/ZrO₂ and (1-*x*) Cu/ZrO₂ catalyst (*x* = 1, 0.79, 0.59, 0.29, 0, sum 0.20 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm. Cu/ZrO₂ (♦), 0.29 Ni/ZrO₂ + 0.71 Cu/ZrO₂ (◆), 0.59 Ni/ZrO₂ + 0.41 Cu/ZrO₂ (◆), 0.79 Ni/ZrO₂ + 0.21 Cu/ZrO₂ (◆), Ni/ZrO₂ (◆).

The TOF (**Figure 4-7**) for the decarbonylation was higher on co-impregnated Ni_xCu_{1-x}/ZrO₂ catalysts than on physical mixed, leading to a more rapid consumption of 1-octadecanol (**Figure 4-9, A**) and higher yields of *n*-heptadecane (**Figure 4-9, B**). For Ni_{0.29}Cu_{0.71}/ZrO₂, **Figure 4-9, B** shows a lower yield of *n*-heptadecane compared to the other two alloys. Hence, the yield of *n*-heptadecane increased with decreasing Cu content. The influence of the electronic promotion effect of Cu becomes more visible through enhanced decarbonylation. After four hours of reaction, nearly quantitative conversion to *n*-heptadecane was achieved for Ni_{0.59}Cu_{0.41}/ZrO₂ and Ni_{0.79}Cu_{0.21}/ZrO₂, when starting with stearic acid. In the same time, less than 10% of *n*-heptadecane was formed on Ni/ZrO₂.

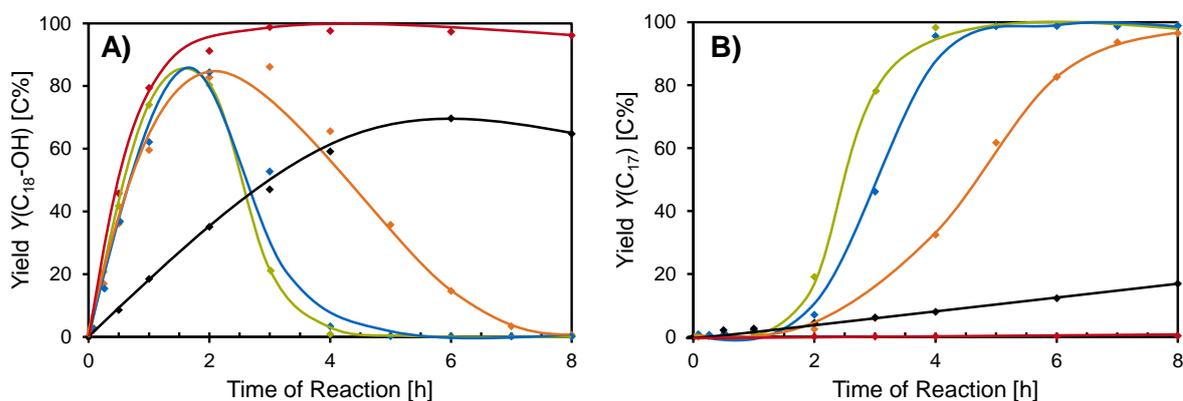

Figure 4-9. Yield of 1-octadecanol over Ni_xCu_{1-x}/ZrO₂ (A) and yield of *n*-heptadecane over Ni_xCu_{1-x}/ZrO₂ (B) as a function reaction time. Reaction conditions: Stearic acid (0.5 g), Ni_xCu_{1-x}/ZrO₂ catalyst (*x* = 1, 0.79, 0.59, 0.29, 0, 0.20 g), dodecane (100 mL), 260 °C, *p*(H₂) = 40 bar, stirring at 600 rpm. Cu/ZrO₂ (♦), Ni_{0.29}Cu_{0.71}/ZrO₂ (◆), Ni_{0.59}Cu_{0.41}/ZrO₂ (◆), Ni_{0.79}Cu_{0.21}/ZrO₂ (◆), Ni/ZrO₂ (◆).

On pure Ni catalyst (*e.g.* Ni/ZrO₂) stearic acid is hydrodeoxygenated to 1-octadecanol and further decarbonylated to alkane.⁷⁻⁸ In presence of Cu, the first step, the hydrodeoxygenation is enhanced by nearly a factor of eight. The decarbonylation (cleaving a C–C bond) was however, not affected by Cu.²² The higher electron density of Ni in Ni_xCu_{1-x} alloy accelerates the decarbonylation of octadecanal to *n*-heptadecane by a factor of four to six (**Figure 4-7**) compared to Ni/ZrO₂. Therefore, the content of Ni and Cu has to be balanced in order combine high conversion rates with a high yield of *n*-heptadecane.

4.4 Conclusions

The physical or chemical mixture of Ni and Cu metal supported on ZrO₂ led to catalysts converting stearic acid to long chain alkanes more efficiently than monometallic Ni/ZrO₂. The conversion rate of stearic acid increased linearly with increasing content of Cu concentration and the selectivity of 1-octadecanol was nearly 100% under initial conditions, independent from the content of Cu and the preparation method. The higher electron density of Ni in Ni_xCu_{1-x}/ZrO₂ enhanced the rate of decarbonylation up to six times compared to Ni/ZrO₂. Too high Cu concentrations in the alloy, however, reduced the rate of *n*-heptadecane formation (not the TOF), because of the lower concentration of nickel available at the surface. Thus, the present catalyst demonstrates how two functions can be combined in this bimetallic catalyst to optimize the conversion of carboxylic acids to alkanes.

4.5 Experimental Section – Materials and Methods

4.5.1 Chemicals

All chemicals, *i.e.*, Zr(OH)₄ × H₂O (XZO 1247/01, MEL Chemicals), Ni(NO₃)₂ × 6 H₂O (Acros Organics, ≥98.5%), Cu(NO₃)₂ × H₂O (Sigma-Aldrich, 99.999%), synthetic air (20.5% O₂/ 79.5% N₂, Westfalen), hydrogen (Westfalen, 99.9999%), argon (Westfalen, 99.9999%), stearic acid (Sigma-Aldrich, ≥99.5% analytical standard), 1-octadecanol (Sigma-Aldrich, ≥99.5% Selectophore™), *n*-octadecane (Sigma-Aldrich, 99%), *n*-heptadecane (Sigma-Aldrich, 99%), dodecane (Sigma-Aldrich, ≥99%, ReagentPlus), were purchased commercially and were not further purified.

4.5.2 Catalyst preparation

The support ZrO₂ material was prepared by calcination of Zr(OH)₄ × H₂O at 400 °C in ambient air for 4 h (heating rate: 10 °C min⁻¹). Bimetallic Ni_xCu_{1-x}/ZrO₂ catalysts with five different Ni_xCu_{1-x}-ratios and a total metal loading of 10 wt% were prepared by wetness impregnation. Ni(NO₃)₂ × 6 H₂O and Cu(NO₃)₂ × H₂O (**Table A 4-1**) were dissolved in de-ionized H₂O (5.0 g), and the resulting solution was added dropwise to the support under stirring in ambient air (co-impregnation). The slurry was further stirred for 4 h, followed by drying at 110 °C overnight. Subsequently, the ground solid was calcined in synthetic air (flow rate: 100 mL min⁻¹) at 450 °C for 4 h (heating rate: 2 °C·min⁻¹) and reduced in H₂ flow (flow rate: 100 mL min⁻¹) at 500 °C for 4 h (heating rate: 2 °C min⁻¹).

4.5.3 Catalyst characterization

X-Ray powder diffraction (XRD) was performed on a Philips X'Pert Pro and a PANalytical Empyrean System equipped with a Cu Kα radiation source (40 kV/45 mA) with a step size of 0.01711° and a scan rate of 1.08° min⁻¹ in the 2θ range of 5–70°; with a step size of 0.0131303° and a scan rate of 0.002205° min⁻¹ in the 2θ range of 42–47° using Kα1). The particle size of Ni- and Cu-metal clusters was determined from peak broadening of Ni(111) and Cu(111) reflex, fitted with HighScore Plus program,¹² using the Scherrer equation. Deconvoluted diffraction patterns resulted by subtracting the diffractogram of the ZrO₂-support normalized to the maximum intensity of the *m*-ZrO₂ peak from the diffractogram of Ni_xCu_{1-x}/ZrO₂ catalyst normalized to the maximum intensity of the *m*-ZrO₂ peak.

N₂-sorption: For measurement of the BET surface area, the sample was activated in vacuum at 250 °C for 2 h before measurement. The adsorption of N₂ was performed at -196 °C by using the Sorptomatic 1990 series instrument.

H₂-chemisorption: After reducing the Ni based catalyst samples in H₂-flow at 450 °C for 1 h, they were evacuated at 300 °C for 1 h. The H₂ adsorption isotherms accounting for both chemisorption and physisorption were measured on a Thermo Scientific's Surfer instrument at a pressure ranging from 9 to 400 mbar at 25 °C. For removing physisorbed H₂, the system was evacuated for 20 min afterwards. By extrapolating the isotherm to zero H₂-pressure, the concentration of chemisorbed hydrogen on the metal was determined. The Ni

dispersion was derived by assuming an average surface Ni to H ratio of 1. Furthermore, it is assumed that Cu does not chemisorb H₂.¹¹

Temperature programmed desorption (TPD) of ammonia and carbon dioxide was carried out in a parallel reactor system (six fold). A prior activation of the pressed samples (500-710 μm) in He at 500 °C for 1 h was conducted. Consequently, the sample was evacuated at 10⁻² mbar the adsorbent NH₃ or CO₂ was loaded at a partial pressure of 1 mbar and 100 °C or 40 °C, respectively. The sample was then purged with He for 1 h in order to remove physisorbed molecules. After activation, the six samples were heated from 100 to 770 °C with a rate of 10 °C·min⁻¹ to desorb NH₃ and from 40 to 700 °C to desorb CO₂. The signals were detected by a Balzer QME 200 mass spectrometer. For calibration purposes, NH₃ was desorbed from a HMFI-90 standard and CO₂ generation from NaHCO₃ decomposition was used for CO₂ calibration.

Atomic absorption spectroscopy (AAS) was used to determine the Ni and Cu content of the catalysts with a ThermoFisher Solaar M5 AA-Spectrometer. Prior to Ni and Cu determination, the catalysts were dissolved in a mixture of HF, HNO₃ and boiling concentrated H₂SO₄.

IR spectroscopy of adsorbed CO was performed on a Bruker VERTEX 70 spectrometer at a resolution of 2 cm⁻¹ with 128 scans in the range of 1000-4000 cm⁻¹. For the measurements, the samples were pressed into self-supporting wafers and mounted in the sample holder. The Ni-Cu/ZrO₂ catalysts were activated in H₂-flow at 450 °C for 1 h, and then subsequently outgassed under vacuum ($p = 10^{-7}$ mbar) to remove H₂ while cooling to 40 °C. The adsorption of CO was performed at 0.3 mbar until equilibrium was reached, then evacuated ($p = 10^{-7}$ mbar) for 5 min to remove physisorbed and gas phase CO. The IR spectra of adsorbed CO were obtained by subtracting the activated sample, and then were normalized by the weight of the Ni in the respective wafer.

4.5.4 Catalyst activity and kinetic measurement

Catalytic reactions were carried out in an autoclave (Parr, 300 mL). Stearic acid or 1-octadecanol, catalyst and 100 mL dodecane were loaded into the autoclave and pressurized with H₂ (3 × 20 bar). Typically, the reaction was carried out at 260 °C in presence of

40 bar H₂ at a stirring speed of 600 rpm. *In situ* sampling was performed during the reaction. Typically, each sample of max. 0.5 mL was withdrawn from the reaction slurry and filtered through a 2 μm filter at the bottom of the reactor in order to make sure that the sample is free of catalyst, that the reaction in the sample vial is stopped and that the mass of catalyst in the reactor stays constant. The dead volume between filter and end of the sampling tube (0.05 mL) was flushed and discarded prior to every sampling. The liquid samples were analyzed by a Agilent 7890B GC system, equipped with a flame ionization detector (FID) and Agilent 5977 MS detector, using a HP-5 capillary column (30 m, 0.32 mm inner diameter, 0.25 μm film). Quantification error is less than ±5% for all experiments.

Conversion = (weight of converted reactant / weight of the starting reactant) × 100%.
Yield (C%) = (C atoms in each product / C atoms in the starting reactant) × 100%. Selectivity (C%) = (C atoms in each product/sum of C atoms in all the products) × 100%. The initial reaction rate was deduced from the slope of the linear fit to the conversion *versus* time plot in the linear region at low conversions (<20%). Rate = mole of converted reactant/ mass of catalyst / reaction time. TOF = rate / mole of accessible Ni on the catalyst's surface = mole of converted reactant / mole of accessible Ni on the catalyst's surface / reaction time.

4.6 Contributions

In addition to the author of this thesis, Christoph Denk carried out the full conversion experiments of physical mixed x Ni/ZrO₂ + (1- x) Cu/ZrO₂ catalysts and the experiments with 1-octadecanol as starting material. Eszter Baráth drew the graphical abstract.

4.7 Appendix

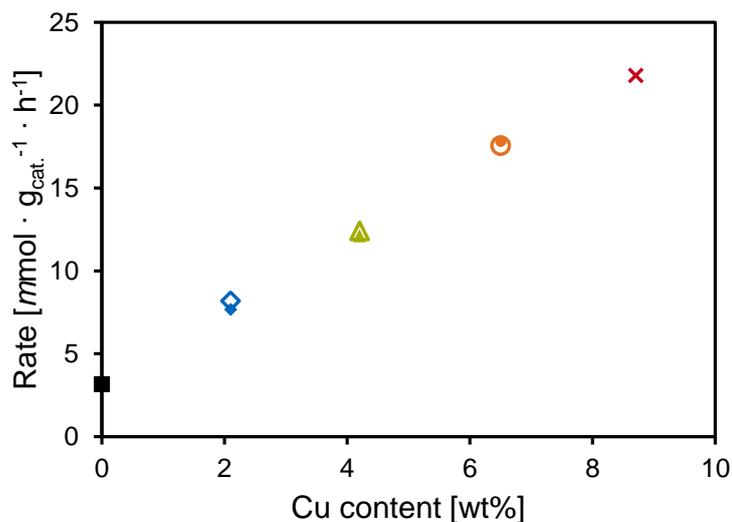

Figure A 4-1. Initial reaction rate for the hydrodeoxygenation of stearic acid over physical mixtures of monometallic x Ni/ZrO₂ and $(1-x)$ Cu/ZrO₂ and co-impregnated Ni _{x} Cu _{$1-x$} /ZrO₂ as a function of Cu content. Total wt% metal (= Ni+Cu) is 10 wt%. Reaction conditions: stearic acid (0.5 g), Ni-Cu/ZrO₂ (0.05 g), dodecane (100 mL), 260 °C, $p(\text{H}_2) = 40$ bar, stirring at 600 rpm. Cu/ZrO₂ (×), 0.29 Ni/ZrO₂ + 0.71 Cu/ZrO₂ (○), 0.59 Ni/ZrO₂ + 0.41 Cu/ZrO₂ (▲), 0.79 Ni/ZrO₂ + 0.21 Cu/ZrO₂ (◆), Ni/ZrO₂ (■), Ni_{0.29}Cu_{0.71}/ZrO₂ (○), Ni_{0.59}Cu_{0.41}/ZrO₂ (▲), Ni_{0.79}Cu_{0.21}/ZrO₂ (◆).

Chapter 5

Conclusions and Outlook

Renewable diesel can be produced from microalgae oil and is therefore envisioned as a promising third generation sustainable energy carrier. The potential for increasing the rate of stearic acid conversion of a supported and bi-functional hydrodeoxygenation catalyst and enhancing the selectivity towards desired products was demonstrated. Although it is difficult to differentiate contributions caused by the oxide from those of the metal in supported metal catalysts, the support's properties were separately investigated from the state of the active metals. Due to thorough catalyst characterization, dependencies of the reaction results on catalyst properties could be derived.

One key towards increasing the activity is the role of the support. Bare ZrO_2 support alone is active for the hydrodeoxygenation of stearic acid. The crystal phase of the support has an effect to the overall rate that was deduced to be related to significantly higher adsorption of carboxylic acid on *monoclinic* ZrO_2 than *tetragonal* (Chapter 2). This was measured by IR spectroscopy due to higher concentration of oxygen defects, which were quantified by isotope exchange experiments (TPIE) and the ability of dissociating H_2 . From that, a correlation of reaction rate and phase composition of ZrO_2 and a three times higher activity of stearic acid hydrogenation on $\text{Ni}/m\text{-ZrO}_2$ than on $\text{Ni}/t\text{-ZrO}_2$ could be derived. The experimentally determined reaction rate constants were comparable with fitted values for individual reactions.

In this thesis, the investigations of the support were focused on ZrO_2 . Furthermore, the addition of SiO_2 , substituted into the crystal lattice of ZrO_2 , was forming a binary oxide, increasing the specific surface area of the support, forming novel nano-layered spherical particles and generating Brønsted acid sites (Chapter 3). In proximity of Ni, those BAS promote the conversion of stearic acid. Moreover, the reaction pathway is controlled towards dehydration, increasing the selectivity of *n*-octadecane over *n*-heptadecane.

Furthermore, the impact of the active metal site was enhanced without the use of precious metals (Chapter 4). The addition of Cu to Ni (both base metals) increased the rate of 1-octadecanol formation from stearic acid – hence enhancing the first step of the reaction sequence. Mixing Ni with Cu resulted in the formation of a $\text{Ni}_x\text{Cu}_{1-x}$ -alloy with higher electron density at Ni. This catalyzes the decarbonylation of 1-octadecanol to alkane more rapidly, leading to higher yield of *n*-heptadecane. On pure Cu/ZrO₂ no alkanes are formed.

In this thesis, catalysts were developed that increased the rate for the hydrodeoxygenation of stearic acid by an order of magnitude. The perceptions of this work can make a valuable contribution to the mild production of third generation biofuels. They offer magnificent potential for new means of novel catalyst design. Although not explicitly mentioned, the catalysts described in this work are stable and recyclable. In order to develop those systems towards large-scale use and technical application, further investigations in a continuous system are required.

Moreover, many other preparation techniques for advanced ZrO₂ supports with beneficial properties (*e.g.* specific surface area, pore distribution, concentration-, strength- and type of acid sites) that deserve investigation in more depth. Analog, the dispersion of Ni can be increased by alternative preparation conditions leading to a higher rate of hydrodeoxygenation as well. Here, a more homogenous particle size distribution would reduce the scatter of the experimental results.

Chapter 6

Schlussfolgerungen und Ausblick

Erneuerbarer Diesel kann aus Mikroalgenöl hergestellt werden und gilt als vielversprechender und nachhaltiger Energieträger der dritten Generation. In dieser Arbeit wurden Möglichkeiten gezeigt, wie die Reaktionsgeschwindigkeit auf geträgerten und bifunktionalen Katalysatoren für die Hydrodeoxygenierung erhöht und die Selektivität zu erwünschten Produkten verbessert werden kann. Obwohl es bei geträgerten Metallkatalysatoren schwierig ist, die Beiträge des Oxids von denen des Metalls zu differenzieren, wurden die Eigenschaften des Trägers getrennt vom Zustand des aktiven Metalls untersucht. Durch gründliche Charakterisierung der Katalysatoren konnten Ursachen der Reaktionsergebnisse von den Katalysatoreigenschaften ab- und hergeleitet werden.

Der Träger nimmt eine Schlüsselrolle ein um die Aktivität des Katalysators zu erhöhen. ZrO_2 Träger alleine ist bereits für die Hydrodeoxygenierung von Stearinsäure aktiv. Die Kristallphase des Trägers hat einen Einfluss auf die Gesamtrate, was von der signifikant höheren Adsorption der Carboxysäure auf *monoklinem* im Vergleich zu *tetragonalem* ZrO_2 hergeleitet wurde (Kapitel 2). Dies wurde mittels IR Spektroskopie durch eine höhere Konzentration von Sauerstoffdefektstellen gemessen, welche durch Isotopenaustauschexperimente und die Dissoziationsfähigkeit von H_2 quantifiziert wurden. Daraus lässt sich eine Korrelation der Reaktionsrate mit der Phasenzusammensetzung von ZrO_2 und eine dreimal höhere Aktivität der Hydrierung von Stearinsäure auf $\text{Ni}/m\text{-ZrO}_2$ als auf $\text{Ni}/t\text{-ZrO}_2$ ableiten. Die experimentell bestimmten Reaktionskonstanten waren mit den numerisch bestimmten Werten der einzelnen Reaktionen vergleichbar.

Die Untersuchungen des Trägers waren in dieser Arbeit auf ZrO_2 konzentriert. Des Weiteren wurde durch Zugabe von SiO_2 – eingebaut in das Kristallgitter von ZrO_2 – ein binäres Oxid gebildet, welches die spezifische Oberfläche des Trägers erhöht, neuartige runde Partikel mit Nano-Schichtstruktur bildet und Brønsted-Säure-Zentren generiert (Kapitel 3). In der Nähe von Ni erhöhen diese Brønsted-Säure-Zentren die Umsetzung von

Stearinsäure. Zudem wird der Reaktionspfad zur Dehydratisierung hin gesteuert, was die Selektivität von *n*-Octadecan gegenüber *n*-Heptadecan erhöht.

Weiterhin wurde der Einfluss des aktiven Metallzentrums ohne den Einsatz von Edelmetallen erhöht (Kapitel 4). Durch das Hinzufügen von Cu zu Ni (beides Nichtedelmetalle) wurde die Rate der Bildung von 1-Octadecanol aus Stearinsäure erhöht – folglich wurde der erste Schritt des Reaktionsnetzwerkes verbessert. Durch Mischen von Ni und Cu wurde eine $\text{Ni}_x\text{Cu}_{1-x}$ -Legierung gebildet, die eine höhere Elektronendichte als Ni besitzt. Dadurch wird die Decarbonylierung von 1-Octadecanol zu einem Alkan schneller katalysiert, was zu einer höheren Ausbeute von *n*-Heptadecan führt. Durch reines Cu/ZrO₂ werden keine Alkane gebildet.

In der vorliegenden Arbeit wurden Katalysatoren entwickelt, welche die Reaktionsrate zur Hydrodeoxygenierung von Stearinsäure um mehr als eine Größenordnung erhöhen. Die Erkenntnisse dieser Arbeit können einen wertvollen Beitrag zur Produktion von Biokraftstoffen der dritten Generation unter milden Bedingungen leisten. Sie bieten vielfältige Möglichkeiten, neue Verfahren zur Herstellung neuartiger Katalysatoren zu entwickeln. Auch wenn es nicht ausdrücklich dargestellt wurde, sind die in dieser Arbeit beschriebenen Katalysatoren stabil und mehrfach verwendbar. Um sie für großtechnische Anwendungen nutzbar zu machen, sind weitere anknüpfende Untersuchungen in einem kontinuierlichen Verfahren notwendig.

Darüber hinaus verdienen weitere Präparationsmethoden für hoch entwickeltes ZrO₂ mit vorteilhaften Eigenschaften (z. B. spezifische Oberfläche, Porenverteilung, Konzentration-, Stärke- und Arten von Säurezentren), eine eingehende Untersuchung. Entsprechend kann auch die Dispersion von Ni durch andere Präparationsbedingungen erhöht werden, was zu einer höheren Hydrodeoxygenierungsrate führt. Zudem würde eine homogenere Partikelgrößenverteilung die Streuung der Versuchsergebnisse verringern.

Figure A 2-3. Zr <i>K</i> -edge EXAFS spectra Fourier transforms (FTs) imaginary χ(R) plots of <i>m</i> -ZrO ₂ , and Ni/ <i>m</i> -ZrO ₂ at ambient temperature and the corresponding fit (line).	52
Figure A 2-4. A) Conversion of stearic acid as a function of time. B) Yields of 1-octadecanol and <i>n</i> -heptadecane over Ni/ <i>m</i> -ZrO ₂ as a function of stearic acid conversion. Reaction conditions: stearic acid (1.0 g), Ni/ZrO ₂ (10 wt%, 0.1 g), dodecane (100 mL), 260 °C, <i>p</i> (H ₂) = 40 bar, stirring at 600 rpm. Reproducibility of the rates has been better than ± 5%.	52
Figure A 2-5. IR spectra of adsorbed propionic acid on Ni/ <i>m</i> -ZrO ₂ and Ni/ <i>t</i> -ZrO ₂ , with increasing pressures from 0.02 to 0.05 <i>mbar</i> at 40 °C (A and C), and with increasing temperatures from 100 °C to 250 °C at 0.05 <i>mbar</i> pressure (B and D).	53
Figure A 2-6. XRD of Ni catalysts supported on 2:1-, 1:1-, 1:2-ratio mixture of <i>monoclinic</i> and <i>tetragonal</i> ZrO ₂ .	54
Figure A 3-1. ²⁹ Si-MAS-NMR spectra of SiO ₂ -ZrO ₂ (<i>one-pot</i> hydrothermal) with increasing mol%-SiO ₂ . Details of 6-, 27- and 37 SiO ₂ ZrO ₂ as an enlargement of <i>Q1</i> , <i>Q2</i> and <i>Q3</i> range (top left).	80
Figure A 3-2. Reaction rate and turn over Frequency (TOF) for the conversion of stearic acid as a function of specific surface area (BET). Reaction conditions: stearic acid (0.5 g), Ni/SiO ₂ -ZrO ₂ catalyst (10 wt%, 0.05 g), dodecane (100 mL), 260 °C, <i>p</i> (H ₂) = 40 bar.	81
Figure A 3-3. A) Conversion of stearic acid as a function of time. B) Yields of 1-octadecanol, stearyl stearate, <i>n</i> -heptadecane and <i>n</i> -octadecane over	

Ni/29 SiO ₂ -ZrO ₂ (SiO ₂ Impregnation) as a function of stearic acid conversion. 1-octadecanol (▲), <i>n</i> -heptadecane (◆), <i>n</i> -octadecane (■) and stearyl stearate (×). Reaction conditions: stearic acid (0.5 g), Ni/SiO ₂ -ZrO ₂ catalyst (10 wt% Ni, 0.05 g), dodecane (100 mL), 260 °C, <i>p</i> (H ₂) = 40 bar, stirring at 600 rpm, 2 h.	82
Figure A 4-1. Initial reaction rate for the hydrodeoxygenation of stearic acid over physical mixtures of monometallic <i>x</i> Ni/ZrO ₂ and (1- <i>x</i>) Cu/ZrO ₂ and co-impregnated Ni _{<i>x</i>} Cu _{1-<i>x</i>} /ZrO ₂ as a function of Cu content. Total wt% metal (= Ni+Cu) is 10 wt%. Reaction conditions: stearic acid (0.5 g), Ni-Cu/ZrO ₂ (0.05 g), dodecane (100 mL), 260 °C, <i>p</i> (H ₂) = 40 bar, stirring at 600 rpm. Cu/ZrO ₂ (×), 0.29 Ni/ZrO ₂ + 0.71 Cu/ZrO ₂ (○), 0.59 Ni/ZrO ₂ + 0.41 Cu/ZrO ₂ (Δ), 0.79 Ni/ZrO ₂ + 0.21 Cu/ZrO ₂ (◇), Ni/ZrO ₂ (■), Ni _{0.29} Cu _{0.71} /ZrO ₂ (●), Ni _{0.59} Cu _{0.41} /ZrO ₂ (▲), Ni _{0.79} Cu _{0.21} /ZrO ₂ (◆).	104

Curriculum Vitae

Sebastian Dieter Foraita

Born on February 09, 1987 in Deggendorf

- Since 04/2016 Trainee (Brandreferendar) at the Fire Department of Frankfurt am Main
- 02/2012-03/2016 PhD Student at Technische Universität München, Technische Chemie II, Prof. Dr. Johannes A. Lercher: “Investigation of Ni/ZrO₂ catalysts for the hydrodeoxygenation of microalgae oil”
- 10/2009-11/2011 Master of Science (Chemistry), Technische Universität München
- Technical Chemistry (Major)
 - Construction Chemistry (Minor)
- 04-11/2011 Master’s Thesis, Technische Universität München, Construction Chemistry, Prof. Dr. Johann Plank: “Preparation and characterization of new bio-nanocomposite materials consisting of Creatine respectively microbial polysaccharides and layered double-hydroxides“
- 07-12/2010 Exchange semester, National University of Singapore (NUS)
- 10/2006-08/2009 Bachelor of Science (Chemistry), Technische Universität München
- 03-04/2009 Bachelor’s Thesis, Technische Universität München, Radiochemistry, Prof. Dr. Andreas Türler: “Electrolytic accumulation of tritium in aqueous solutions – Determining the tritium-separation-factor of platinum cathodes“
- 08/1997-06/2006 Robert-Koch-Gymnasium Deggendorf
- Final degree: “Allgemeine Hochschulreife“

Oral presentations

Sebastian Foraita, Eszter Baráth, Chen Zhao, Johannes A. Lercher “Novel sponge shaped high surface area SiO₂-ZrO₂ supports for hydrodeoxygenation of stearic acid with Ni/SiO₂-ZrO₂” DGMK Conversion of Biomass, 12.-14. May 2014, Rotenburg a.d. Fulda, Germany

Sebastian Foraita, Eszter Baráth, Chen Zhao, John L. Fulton, Zizwe A. Chase, Donald M. Camaioni, Aleksei Vjunov, Johannes A. Lercher “Effect of Zirconia Morphology of Ni/ZrO₂ for Stearic Acid Hydrodeoxygenation” 247th American Chemical Society National Meeting & Exposition, 16.-20. March 2014, Dallas (TX), USA

Poster presentations

“Effect of ZrO₂ morphology and novel doughnut shaped high surface area supports for hydrodeoxygenation of stearic acid with Ni/ZrO₂” Sebastian Foraita, Eszter Baráth, Chen Zhao, Johannes A. Lercher, 47th Annual Meeting German Catalysis Society, March 2014, Weimar, Germany

“The Impact of Zirconia Morphology on Hydrodeoxygenation of Stearic Acid with Ni/ZrO₂” Sebastian Foraita, Chen Zhao, Johannes A. Lercher, 46th Annual Meeting German Catalysis Society, March 2013, Weimar, Germany

“The Support Influence and the Role of Zirconia Morphology on Hydrodeoxygenation of Stearic Acid over Ni/ZrO₂” Sebastian Foraita, Chen Zhao, Johannes A. Lercher, 6th IDECAT/ERIC-JCAT Conference on Catalysis, March 2013, Brixen, Italy

“Selective transformation of algae oil to diesel range alkanes with Ni/ZrO₂” Baoxiang Peng, Sebastian Foraita, Chen Zhao, Johannes A. Lercher, 15th International Congress on Catalysis, July 2012, Munich, Germany

“Hydrocarbon biodiesel production from microalgae oil with Ni/zeolite” Baoxiang Peng, Sebastian Foraita, Chen Zhao, Johannes A. Lercher, Energy Challenges 2050, Munich School of Engineering, June 2012, Munich, Germany

Statutory Declaration

I declare that I have authored this thesis independently, that I have not used other than the declared sources and resources, and that I have explicitly marked all material which has been quoted either literally or by content from the used sources. At the end of each chapter all collaborators are listed and their specific contribution is addressed. Published content of this thesis is clearly marked at the beginning of each chapter and reused according to the terms of the publisher. The content of chapter 4 is about to be published as well.

München, _____
