Die Dissertation wurde am 18.11.2013 bei der Technischen Universität München eingereicht und durch die Fakultät für Chemie am 11.12.2013 angenommen.

This thesis has been performed in the time between November 2010 and November 2013 at the research group Molecular Catalysis of Technische Universität München.

I would like to express my deep gratitude to my academic supervisor Herrn Prof. Dr. Fritz E. Kühn

For his continuous supervision, encouragement and trust in my work.

## Acknowledgements

I would like to give my deepest gratitude to my adacemic supervisor, Prof. Dr. Fritz E. Kühn for giving me the opportunity to work in his research group as a PhD candidate, for his encouragement and trust in me and my work, and for all the support which were crucial for the success of this PhD thesis.

I would also like to express my gratitude to Dr. Mirza Cokoja for proof-reading my written work and continuous help.

My heartfelt gratitude goes to Prof. Dr. János Mink from the Hungarian Academy of Sciences for his kind and friendly personality and the invaluable scientific discussions, which intrigued me a lot in learning Infrared and Raman spectroscopies and applications. His co-workers Judith Mihály, Csaba Németh and László Hajba are also greatly acknowleged for their help and organization of the Raman and IR equipment in their institute in Budapest.

I sincerely thank Dr. Eberhardt Herdtweck and Dr. Alexander Pöthig for their X-ray crystallographic measurements and contribution to my manuscripts; Thomas Schröferl for his help in GC measurement and frequent discussion to solving the problems that we have come across; Georgeta Krutsch and Jürgen Kudermann for the NMR measurement and their friendly personality; elementary analysis technicians Ulrike Ammari, Petra Ankenbauer and Bircan Dilki for their kindly and efficient work; Rodica Dumitescu and Burghard Cordes for the MS measurement; Martin Schellerer for handing the chemicals.

I genuinely thank Dr. Mingdong Zhou, Dr. Yang Li, Dr. Mei Zhang-Presse, Dr. Li Min Serena Goh, Dr. Manuel Högerl, Dr. Sin Ying Tina Lee, Dr. Typhène Michel and Dr. Antoine Monassier for their help, friendship and pleasant time during the start of my PhD years.

I would also like to thank my all colleagues: Dr. Markus Drees, Dr. Philipp Altmann, Dr. Mathias Köberl, Dr. Simone Hauser, Dr. Jenny Ziriakus, Dr. Arne Schaper, Dr. Daniel Betz, Dr. Barnali Dutta, Julia Witt, Esther Bayon, Sara Abbassi, Mario Bitzer, Nidhi Grover, Amylia Abdul Ghani, Valentina A. Korinth, Korbinian Riener, Xumin Cai, Daniel Wei $\beta$, Domink Höhne, Markus Anneser, Eva Hahn, Xuhui Wei, Michael Anthofer, Lilian Graser, Reentje Harms, Stefan Huber, Dominik Jantke, Iulius Makovits, Andreas Raba, Rui Zhong, Thomas

Wagner, Wilhelm Michael, Marlene Möller, Christian Münchmeyer, Sophie Jürgens for all the help in the everyday life in the laboratory and for the pleasant working atmosphere they created.

Acknowledgments also go to all the secretaries of the group: Irmgard Grötsch, Renate Schuhbauer-Gerl, Roswitha Kaufmann and Ulla Hifinger for their help with organization and office matters.

I would also like to express my appreciation to the memorable time at the chemistry practicals in Weihenstephan with Prof. Dr. Peter Härter, Tobias Kubo and Peter Richter.

I heartily thank my parents and my family for their endless love and continuous encouragement. My deepest gratitude belongs to my husband Su Li for his love and support.

To my family
With deep gratitude and love

#### Abstract

Ionic liquids (ILs) have received great attention in recent years as solvents or catalysts due to their unique properties. This work focused on developing a cheap, environmentally benign, recyclable ILs system for epoxidation and sulfoxidation.

This thesis is divided into three parts, which present the results that have been discovered within three years of research.

\section*{Imidazolium perrhenate ionic liquids}

Imidazolium-based ionic liquids (ILs) containing perrhenate anions were synthesized and characterized. In addition, their catalytic activity was examined in epoxidation of olefins and oxidation of sulfides. The results show that ILs containing perrhenate are very efficient reaction media and catalysts for these two oxidation reactions with hydrogen peroxide as oxidant, thus affording good yield of the corresponding product. A deeper understanding of the mechanism of the oxidation systems was obtained by investigations with Raman, IR, NMR spectroscopy and DFT calculation. Hydrogen bonds between the oxidant and perrhenate activate the oxidant, thereby leading to the transfer of an oxygen atom to the substrates such as olefins or sulfides, demonstrating the special features of ILs as a reaction environment.

## Ionic liquids with weakly coordinating anions

A protocol for oxidation of sulfides to sulfoxides mediated by ILs with weakly coordinating anions $\left(\left[\mathrm{BF}_{4}\right]^{-}\right.$and $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}\left(\mathrm{Ar}^{\mathrm{F}}=\mathrm{C}_{6} \mathrm{~F}_{5}, 3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)$ was established. Besides their catalytic performance, the mechanism of oxidation system was also investigated. The hydrogen bond formation between the IL anion and the oxidant appears to be the crucial step during the oxidation reaction.

## Transition metal catalysts in ionic liquids

New transition metal compounds, Schiff-base complexes of methyltrioxorhenium (VII) and polyoxometalates salts are used as catalysts for epoxidation and sulfoxidation with ILs as solvents under mild conditions. Currently available catalytic systems provide an environmentally benign and sustainable way for oxidation reactions.

## 1 Introduction

### 1.1 Ionic liquids

In recent years, the growing awareness of environmental issues has brought attention on the need for "greener" and more sustainable technologies in chemical industry. ${ }^{[1]}$ The chemistry community has been urged to develop new reaction pathways that are less hazardous to human health and environment. ${ }^{[2]}$ Due to the necessity of solvents for most homogeneous reactions, alternative, less harmful solvents have been developed. The ideal solvent should have very low volatility, be easy to handle and recycle, have a wide liquid range, and be chemical and physical stable. In these respects ionic liquids (ILs) appear to be good candidates.

Ionic liquids (ILs) have received great attention due to their unique properties, such as non-volatile nature, non-measurable vapor pressure, broad liquid temperature ranges, ability to dissolve a wide range of inorganic and organic compounds. ${ }^{[3]}$ Thus, ILs have commonly been quoted as "green" replacements for organic solvents for industrial process and their overall environmental impact. ${ }^{[4]}$
The first IL, $\left[\mathrm{Et}_{4} \mathrm{~N}\right]\left[\mathrm{NO}_{3}\right]$, was reported by Walden already in $1914 .{ }^{[5]}$ Later, Hurely et al. developed the first room temperature IL from $[\mathrm{Emim}] \mathrm{Cl}-\mathrm{AlCl}_{3}$ system for aluminium electroplating in $1948 .{ }^{[6]}$ However, these chloroaluminate-based IL systems were brought to a more general audience by the groups of Osteryoung and Wilkes only in the 1970s. The scope was extended by the groups of Hussey and Seddon in 1980s, mainly for electrochemical and spectroscopic studies. ${ }^{[7]}$ In 1972, Parshall et al. developed ILs based on tetraalkylammonium chlorostannate with dissolved $\mathrm{PtCl}_{2}$ as a reaction medium for several homogeneous catalytic reactions of olefins. ${ }^{[8]}$ In 1992, Wilkes' group again received a major breakthrough in IL chemistry by the discovery of air- and moisture-stable imidazolium salts with anions such as $\left[\mathrm{BF}_{4}\right]^{-}$and $\left[\mathrm{PF}_{6}\right]^{-[9]}$ leading to the diversification of ILs with numerous combinations of cations and anions. At the onset of the new millennium, the concept of task-specific ionic liquids was introduced by Davis. ${ }^{[10]}$ These compounds are defined as ionic liquids in which the anion, cation, or both covalently incorporate a functional group (designed to endow them with particular properties, either physical or chemical or in terms of reactivity) as a part of the ion structures. Today, there are up to $10^{18}$ kinds of ionic liquids that can in principle be produced, which present enormous opportunities to design or optimize the most suitable system for specific catalytic processes (Figure 1).

Typical Cations:

$\mathrm{BF}_{4}{ }^{\ominus}$
$\mathrm{NO}_{3}{ }^{\ominus}$
$\mathrm{HCO}_{2}^{\ominus}$
$(\mathrm{RO})_{2} \mathrm{PO}_{4}{ }^{\ominus}$
Typical Anions:

Figure 1. Typical cations and anions in ionic liquids.

Ionic liquids are not only used as green solvent, but also act as catalysts, catalysts activator, or co-catalysts for different reactions. In some of the more recent examples found in the literature, ILs are deliberately prepared so that one of the ions serves as the catalyst for a specific reaction. ${ }^{[11]}$ Cole and co-workers designed a series of water-stable Brönsted acidic ionic liquids in 2002, ${ }^{[12]}$ and many organic reactions involving esterification, ${ }^{[13]}$ nitration, ${ }^{[14]}$ and acetylation ${ }^{[15]}$ have been preformed with these ionic liquids, resulting in excellent yields and selectivity. Functionalized ionic liquids containing anionic selenium species, $\left[\mathrm{SeO}_{3} \mathrm{Me}\right]^{-}$, have been prepared. ${ }^{[16]}$ These salts have been used as selenium catalysts for the oxidative carbonylation of anilines. Analogously, ionic liquids bearing acid counteranions ( $\left[\mathrm{HSO}_{4}\right]^{-}$or $\left.\left[\mathrm{H}_{2} \mathrm{PO}_{4}\right]^{-}\right)$have been used in catalyzing esterifications as recyclable reaction media. ${ }^{[17]}$ Ionic liquids, containing the function $\mathrm{SO}_{3} \mathrm{H}$, have recently been employed in the oligomerization of various alkenes to produce branched alkene derivatives with high conversions and excellent selectivites. ${ }^{[18]}$ All of these studies offer the possibility of designing suitable catalysts for special reactions.

Another advantage of ILs in catalysis is the immobilization of the catalyst. Besides the
tunable solubility to most organic chemicals, ILs are also able to dissolve a wide range of inorganic and organometallic compounds, and therefore large numbers of catalysts having polar or ionic character can be immobilized in ILs, which can greatly facilitate the separation and subsequent reuse of the catalyst. In addition, the technological integration of ILs with other advanced technologies, including supercritical fluids, electrochemistry, biocatalysis, and nanotechnology, with great potential for growth, has received more and more attention in green catalysis, and for a long period to come, the importance of the ILs as excellent process solvents in these integrated technologies will be gradually recognized. ${ }^{[19]}$

### 1.1.1 Metal-containing ILs

Metal-containing ionic liquids have been used as versatile reaction media, catalysts, catalyst precursors and reagents for various chemical processes. ${ }^{[20]}$ Some metal-based imidazolium salts with m.p. above $100^{\circ} \mathrm{C}$ were also included to provide information about solid state ionic interactions and catalytic properties. Additionally, the presence of metal ions provides many additional properties such as color, geometry, magnetism and the weaker anion-cation interactions. ${ }^{[21]}$ For example, Welton et al. developed imidazolium salts $[\mathrm{Emim}]_{2}\left[\mathrm{MCl}_{4}\right](\mathrm{M}=$ Co or Ni ) with m. p. $90-100{ }^{\circ} \mathrm{C}$ by mixing the corresponding metal chloride with $[\mathrm{Emim}] \mathrm{Cl}$ under dry nitrogen atmosphere. The crystal structure of $[\mathrm{Emim}]\left[\mathrm{CoCl}_{4}\right]$ and $[\mathrm{Emim}]\left[\mathrm{NiCl}_{4}\right]$ showed that extended hydrogen bonding networks observed between the $\left[\mathrm{MCl}_{4}\right]^{2-}$ and ring hydrogens. ${ }^{[22]}$ The $[\mathrm{Rmim}]\left[\mathrm{ZnX}_{2} \mathrm{Y}_{2}\right](\mathrm{R}=\mathrm{Me}, \mathrm{Et}, \mathrm{n}-\mathrm{Bu}$, benzyl; $\mathrm{X}=\mathrm{Y}=\mathrm{Cl}$ or Br or $\mathrm{X}=\mathrm{Cl}, \mathrm{Y}$ $=\mathrm{Br})$ systems are used for the coupling reaction of $\mathrm{CO}_{2}$ and ethylene or propylene oxide to produce cyclic carbonates. ${ }^{[23]}$ The catalytic activities increase with the increasing nucleophilicity of the halide ion.
On the other hand, metal-NHCs-containing ILs with their recent advances in catalytic reactions enrich their potential applications. For example, Shreeve and co-workers synthesized pyrazolyl-functionalized N -heterocyclic carbene complexes of palladium (II) ( $\mathrm{Pd}(\mathrm{Me})(3-$-mesityl-1-(pyrazolylmethylene)imidazolium)chloride) by using a silver (I) N -heterocyclic carbene complex as a ligand transfer reagent. The obtained complex is air- and moisture- stable and was investigated in the Heck reaction of iodobenzene and $n$-butyl acrylate at $120{ }^{\circ} \mathrm{C}$ with a catalyst loading of $2 \mathrm{~mol} \%$. The reaction yielded $n$-butyl (E)-cinnamate in excellent yields. The catalyst was recycled three times without an evident loss of activity. The high catalytic activity and recyclability was obtained due to the strong Pd (II)-carbene bond and the weak Pd (II)-nitrogen bond. The Pd (0) intermediate can easily be formed and is additionally stabilized and activated by the strong $\sigma$-bond between the carbene
electron pair and the Pd centre. ${ }^{[24]}$
It is obvious that ILs provide high reaction rates and specific selectivity in different fields of catalytic applications. However, the problem of leaching effects in the catalysis reaction is produced. In order to avoid this problem, modifying the metal-complex catalyst to make it more alike to IL solvent medium becomes necessary. In this regard, tagging of the IL-functionality (imidazolium cation) to the ligand of metal complex catalysts has been confirmed as a useful technique to prevent catalyst leaching due to the increased ionophilicity towards ILs. ${ }^{[25]}$

### 1.1.2 Industrial applications

The most successful example for an industrial process using ionic liquids technology is probably the BASIL (Biphasic acid scavenging utilizing ionic liquid) process established by BASF in 2002. ${ }^{[26]}$ The BASIL process is used for the production of the generic photoinitator precursor alkoxyphenylphosphines (Figure 2).

Figure 2. The BASIL process

In the conventional process, triethylamine was used to scavenge the acid that was formed in the course of the reaction, but this method made the reaction mixture difficult to handle due to the waste by-product (triethylammonium chloride formed a dense insoluble paste). Thus, a new idea replacing triethylamine with 1-methylimidazole was produced. Forming 1-methylimidazolium chloride ionic liquid can be easily separated out of the reaction mixture as a discrete phase due to form two liquid phases. Additionally, this new process uses a much smaller reactor than the original technology and the space-time yield is increased from 8 kg $\mathrm{m}^{-3} \mathrm{~h}^{-1}$ to $690,000 \mathrm{~kg} \mathrm{~m}^{-3} \mathrm{~h}^{-1}$, as well as the yield increased from $50 \%$ to $98 \%$.

### 1.2 Epoxidation of olefins

The epoxidation of olefins is of high interest in both industry and academia. Epoxides are very important intermediates in the synthesis of numerous fine chemicals, such as perfumes or pharmaceutical compounds, particularly for the synthesis of various polymers. ${ }^{[27]}$ The epoxidation of olefins using peracids $\mathrm{RCO}_{3} \mathrm{H}$ as oxidant was firstly discovered by Russiann chemist N. Prileschajew in 1909. ${ }^{[28]}$ However, peracides are often dangerous (explosive) and must be handled with greatest care. Subsequently, it was found that Lewis acidic transition metal oxo complexes can transfer one oxygen atom to olefins. Therefore, many transition metal complexes have been successfully used to be catalysts toward olefin epoxidation in order to obtain kinds of epoxides.

### 1.2.1 Methyltrioxorhenium (VII) in olefin epoxidation

Among the multitude of organometallic oxidation catalysts, methyltrioxorhenium $\left(\mathrm{CH}_{3} \mathrm{ReO}_{3}\right.$, MTO) has been recognized to be the most active catalyst for olefin epoxidation. Aside from its application as an oxidation catalyst, MTO is also used to catalyze the other reactions, such as olefin epoxidation, oxidation of conjugated dienes, allylic alcoholsand alkynes, aldehyde olefination and olefin metathesis. ${ }^{[29]}$ However, the synthesis of MTO suffers from some disadvantages with respect to large scale applications: ${ }^{[30]} 1$ ) direct alkylation of dirhenium heptoxide $\left(\mathrm{Re}_{2} \mathrm{O}_{7}\right)$ with the non-reducing alkyl-transfer reagent tetramethyltin wastes half of the rhenium by concomitation formation of (catalytically inactive) trimethyltin perrhenate; 2) the very toxic reagent tetramethyltin is necessary to be used. Therefore, the new method replacing the toxic reagent by the methyl zinc acetate as a methylating reagent was developed by Herrmann (Scheme 1). ${ }^{[31]}$

Scheme 1. Formation of MTO employing organozinc compound.

Among all applications of MTO, olefin epoxidation is the most widely investigated reaction. MTO can catalyze the epoxidation of various olefins with hydrogen peroxide which is
environmentally friendly oxidant since water is produced as only byproduct. Moreover the concentration of MTO used in the epoxidation of simple olefins is $0.1 \mathrm{~mol} \%$ at different temperature. ${ }^{[32]}$
Recently, MTO showed high catalytic activity in epoxidation system with urea hydrogen peroxide (UHP) as oxidant and ILs as solvent. ${ }^{[33]}$ The advantages of this oxidation system in ILs are numerous: 1) This system is a homogenous oxidation solution due to good solubility of ILs; 2) The oxidation solution is nearly water-free, so conversion of the substrate yields only the epoxides and not by-product diols; 3) The system of ionic liquids can be recycled for several times, which present a high interest for industrial applications. ${ }^{[34]}$
With respect to mechanistic studies in the epoxidation reaction using MTO as catalyst in different solvent, Herrmann et al. found MTO formed mono- and bis-peroxide complexes with 1 or 2 equivalents of $\mathrm{H}_{2} \mathrm{O}_{2}$. Moreover, the bis-peroxo complex has also been isolated and structurally characterized (Scheme 2). ${ }^{[35]}$

Scheme 2. Formation of the mono- and bis-peroxo species
Experiments with the isolated bis (peroxo) complex $\left(\mathrm{CH}_{3}\right) \mathrm{Re}\left(\mathrm{O}_{2}\right)_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O}$ have shown that it is the active species in olefin epoxidation catalysis and several other catalytic reactions. ${ }^{[36]}$ In situ experiments show that the mon-peroxo complex exits solely in equilibrium with MTO and is also catalytically active in epoxidation processes. Kinetic experiments indicate that the rate constants for the transformation of substrate into their oxidation products by catalysis with the mono- and bis-peroxo complex are of a comparable order of magnitude. ${ }^{[37]}$ The most acknowledge mechanism of the epoxidation of MTO is a bicyclic mechanism involving both mono- and bis-peroxo complexes (Scheme 3).

Scheme 3. Mechanism of the epoxidation of olefin catalyzed by MTO

The results of both cycles indicate that of key mechanistic importance is the formation of the bis (peroxo) rhenium (VII) complex $\left(\mathrm{CH}_{3}\right) \mathrm{Re}\left(\mathrm{O}_{2}\right)_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O}$ from MTO and two equivalents of $\mathrm{H}_{2} \mathrm{O}_{2}$ in a clean reaction, which seems to be one of the most reactive peroxo metal complexes for epoxidation of olelfins. For other rhenium oxides such as $\mathrm{Re}_{2} \mathrm{O}_{7}$, have lower activities for epoxidation due to subsequent hydrolysis $\left(\mathrm{HReO}_{4}\right)$ which does not occur with MTO under the conditions of catalysts. ${ }^{[38]}$ It is interesting to point out that for both cycles, a concerted mechanism is suggested in which the electron rich double bond of the alkene attacks a peroxidic oxygen of $\left(\mathrm{CH}_{3}\right) \mathrm{Re}\left(\mathrm{O}_{2}\right)_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O}$, which has been inferred from experimental data that system may involve a spiro arrangement. ${ }^{[39]}$
However, a drawback of MTO for the epoxidation of olefin was soon discovered: the Lewis acidity of the rhenium center causes hydrolysis and concomitant cleavage of the epoxide ring leading to the formation of by-product diols in the repsence of water. ${ }^{[40]}$ Several methods have been suggested to overcome this problem. An efficient procedure developed to avoid this side reaction requires the use of urea hydrogen peroxide adduct (UHP) as oxidant, which enables epoxidation to be carried out in non-aqueous media. ${ }^{[41-42]}$ Another method is that the aromatic N-base ligands work by coordinating to the Re center, thereby reducing the Lewis acidity of the catalyst and accelerating the catalytic reactions additionally. ${ }^{[43]}$ Nevertheless, the activity of MTO-Lewis base adducts was originally found to be significantly lower than that of MTO itself. ${ }^{[44]}$ Surprisingly, K. B. Sharpless found the excess use of pyridine did not only hamper
the formation of by-product diols but also increased the reaction velocity in comparion to MTO itself as catalyst precursor. ${ }^{[45]}$ Subsequently, 3-cyanopyridine and particularly pyrazole as Lewis bases are found to be more effective and less problematic for epoxidation. ${ }^{[42 \mathrm{~d}, 46]}$ Therefore, many N-base adducts of MTO were isolated and characterized and in several cases employed for olefin epoxidation catalysis. ${ }^{[39]}$ Scheme 4 represents some examples of Lewis base adducts of MTO.

$\mathrm{L} 1=$ quinclidine
$N, N$ '-dimethylpiperazine
p-methoxyaniline urotropine
$\mathrm{L} 2=2,2^{\prime}$-bipyridine
2-(aminometyl) pyridine piperazine 2,2'-bipyridine- N -oxide
2,6-dimethylaniline
2-(p-tolyliminomethyl) phenol
Pyridine- $N$-oxide

1,10'-phenanthroline
2,2'-bipyrimidine
2,2'-bipyridine- N -oxide

Scheme 4. Lewis base adducts of MTO

The activity of the catalytic Lewis base adducts of MTO depends on the choice of Lewis base ligand, most likely due to the ligands stability against oxidation by $\mathrm{H}_{2} \mathrm{O}_{2}$ and the contribution of ligand basicity to the catalytic systems. ${ }^{[47]}$

### 1.2.2 Polyoxometalates in olefin epoxidation

Polyoxometalates (POMs) are a subset of metal oxides that represent a diverse range of molecular clusters with an almost unmatched range of physical properties and the ability to form dynamic structures. ${ }^{[48]}$ POMs were firstly discovered by Berzelius in 1826, ${ }^{[49]}$ and then has been expanded to a huge family. In addition to its fundamental importance, POMs are ubiquitous in chemical research with numerous applications ranging, such as nanotechnology, ${ }^{[50]}$ biology, ${ }^{[51]}$ surfaces, ${ }^{[52]}$ catalysis, ${ }^{[53]}$ supramolecular materials, ${ }^{[54]}$ electronic materials ${ }^{[55]}$ and molecular materials. ${ }^{[56]}$ Generally, the synthesis of POMs clusters

## Chapter 1

is often very simple synthetic manipulations requiring a small number of steps, or even just one step (one-pot syntheses). ${ }^{[57]}$ Some greatest importance synthetic variables in synthesizing such clusters should be attention: 1) concentration/type of metal oxide anion, 2) PH and type of acid, 3) ionic strength, 4) hetroatom concentration, 5) presence of additional ligands, 6) reducing agent and 7) temperature and solvent of the reaction.
It is also well known that POM catalysts are widely used for organic reactions due to catalytic features such as good catalytic activity and selectivity, the feasible design of catalytically active sites and controllable redox and acidic properties at atomic or molecular levels. ${ }^{[58]}$ These characteristics make them economical and environmentally attractive in both academic and industrial applications. For example, ester hydrolysis in water can be greatly enhanced by the catalysis of the POM, $\mathrm{H}_{3} \mathrm{PW}_{12} \mathrm{O}_{40}$, immobilized on organomodified mesoporous silica. This design overcomes the difficulty involved with the use of solid acides by which catalytic activity is often severely deactivated by water. ${ }^{[59]}$ The epoxidation of cis-cyclooctene was investigated with $\left[\mathrm{W}_{2} \mathrm{O}_{11}\right]^{2-}$ as catalyst and hydrogen peroxide as oxidant by Hou and co-workers (Scheme 5). ${ }^{[60]}$

$[\mathrm{HHIm}]_{2}\left[\mathrm{~W}_{2} \mathrm{O}_{11}\right]$

$[\mathrm{HDIm}]_{2}\left[\mathrm{~W}_{2} \mathrm{O}_{11}\right]$

$[\mathrm{HMIm}]_{2}\left[\mathrm{~W}_{2} \mathrm{O}_{11}\right]$

Scheme 5. The anion $\left[\mathrm{W}_{2} \mathrm{O}_{11}\right]^{2-}$ functionalized catalysts

It was found that $[\mathrm{HDIm}]_{2}\left[\mathrm{~W}_{2} \mathrm{O}_{11}\right]$ can be regarded as a reaction-induced phase-seperation catalyst, which was proved to be the most active catalyst. A noteworthy fact is that the catalytic system switched the reaction mixture from triphase to emulsion, then to a biphasic system, leading the catalyst self precipitated from the reaction at the end of the reaction.

### 1.2.3 Industrial processes

Epoxides, particularly ethylene and propene oxide, are key raw materials of a side variety of chemicals and are often applied as building blocks for polymers. In 1993, the worldwide production capacity for propylene oxide was about $4.0 \times 10^{6}$ tonnes per year of which 1.7, 1.4 and $0.36 \times 10^{6}$ tonnes per year in the USA, Western, Europe and Japan, respectively. ${ }^{[61]}$ The
traditional route proceeds via the conversion of propylene to chloropropanols (Scheme 6).

Scheme 6. The chlorhydrine process
The reaction is performed at $30-35^{\circ} \mathrm{C}$ and 2-3 bar of pressure using aqueous solution chlorine as oxidant. The resulting chlorhydrine is in situ dehydrochlorinated to propylene oxide using basic solution of NaOH or $\mathrm{Ca}(\mathrm{OH})_{2}$. Afterwards, the propylene oxide is distilled out of the reaction mixture to avoid direct hydration. Due to the environmental pressure (toxic chlorine) and huge amount of by-products, a new direct oxidation route was developed in 1967 using organic hydroperoxides as oxidant agent and different tranisition-metal catalysts. ${ }^{[62]}$ Until 1983, the breakthrough was made by Enichem. ${ }^{[63]}$ The system using a titanium-substituted silicalite (TS-1) catalyst which has a hydrophobic surface was developed, moreover, this catalyst has been proved to be effective to a variety of liquid-phase oxidation with the environmental hydrogen peroxide. Based on this technology, BASF, Dow and Solvay developed the HPPO (hydrogen peroxide to propylene oxide) process for the production of propylene oxide. Water is the co-product of this reaction. Hydrogen peroxide is converted completely and the propylene conversion is nearly quantitative. The crude propylene oxide product is purified by distillation. Additionally, methanol can be recycled.
HPPO has significant environmental benefits versus the conventional processes: 1) wastewater is reduced by up to $80 \% ; 2$ ) energy use is reduced by $35 \% ; 3$ ) the simple raw material integration and avoidance of co-products reduces the infrastructure and physical footprint of the plant significantly.

### 1.3 Oxidation of sulfides

Organic sulfoxides and sulfones are useful synthetic intermediates for the construction of various chemically and biologically active molecules, including drugs, ${ }^{[64]}$ flavors, ${ }^{[65]}$ germicides, ${ }^{[66]}$ cardiotonic agents, ${ }^{[67]}$ vasodilators, ${ }^{[68]}$ and catabolism regulators. ${ }^{[69]}$ The oxidation of sulfides is the most straightforward method for the synthesis of sulfoxides and sulfones. The sulfur atom can be easily oxidized by different electrophilic oxidants, but special conditions must be set up to chemoselectively obtain sulfoxides or sulfones. ${ }^{[70]}$ Due to a great interest of theses compounds, different synthetic methods have been developed for
chemoselective oxidation of sulfides.

### 1.3.1 Catalyst-free sulfoxidation

The oxidation of sulfides to the corresponding the sulfoxides by the use of hydrogen peroxide in acetone and acetic acid were initially developed by Gazdar in $1908 .{ }^{[71]}$ Since that time, many sulfoxides were obtrained through their procedure. ${ }^{[72]}$ In 1981, Drabowica et al. observed that use of methanol instead of acetone as the solvent for oxidation of sulfides to sulfoxides with $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant agent decreased the reaction time from 24 h to 18 h (Scheme 7). ${ }^{[73]}$

Scheme 7.Oxdaiton of sulfides to sulfoxides in methanol

However, many functional groups in the sulfides were easily destroyed in this system. In this case, Ravikumar et al. found the transformation of various sulfides into sulfoxides by $\mathrm{H}_{2} \mathrm{O}_{2}$ in hexafluoro-2-propanol (HFIP) as solvent. ${ }^{[74]}$ The results showed that the oxidation reactions in HFIP proceed smoothly with high yield of sulfoxides. However, this system was severely restricted in practical organic synthesis by using poisonous HFIP as solvent due to environmental pressure. After several years, Xu et al. developed a new, convenient and selective oxidation method of some alkyl phenyl sulfides to the corresponding sulfoxides using hydrogen peroxide as oxidant agent in phenol at room temperature. ${ }^{[75]}$ This system was proved to be a highly efficient and selective for the oxidation of various sulfides within a short reaction time. Additionally, the functional groups, even including the highly reactive aldehyde group, were not affected. Recently, a simple and environmentally benign method for oxidation of sulfides with hydrogen peroxide as oxidant agent was introduced by Liu and co-workers. ${ }^{[76]}$ This method can achieve approximatively stoichiometric transformation for some sulfides, resulting an excellent selectivity for sulfoxides under mild conditions.

## Chapter 1

### 1.3.2 Transition-metal catalysts in sulfoxidation

A wide variety of transition metal-catalysts are utilized for oxidative transformations in oxidation of sulfides to sulfoxides or sulfones. Transition metals are activated by, or serve to activate a terminal oxidant, such as dioxygen, superoxide, radicals and peroxides. This section focused on the some transition metal-catalyzed oxidation of sulfides with peroxides.
The catalysts containing molybdenum and tungsten such as $\mathrm{MoO}_{2} \mathrm{Cl}_{2}$, ${ }^{[77]} \mathrm{LiNbMoO}_{6},{ }^{[78]}$ $\left.\left[\mathrm{n}-\mathrm{C}_{4} \mathrm{H}_{9}\right]_{4} \mathrm{~N}\right]_{4}\left(\alpha-\mathrm{Mo}_{8} \mathrm{O}_{26}\right),{ }^{[79]}\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\left(\mathrm{n}-\mathrm{C}_{16} \mathrm{H}_{33}\right)\right]_{3} \mathrm{PO}_{4}\left[\mathrm{~W}(\mathrm{O})\left(\mathrm{O}_{2}\right)_{2}\right]_{4}{ }^{[80]}$ and $\mathrm{W}(\mathrm{CO})_{6}{ }^{[81]}$ have been widely used for the oxidation of sulfides. Additionally, the neutral hexamethylphosphoric triamide complexes of both molybdenum and tungsten diperoxo species, were extensively studied for the oxidation of sulfides. ${ }^{[82]}$ It is important to note that the differences in the speciation and acidity of these two metal ions can lead to minor variations in the reactivity. For example, the tungsten complex has a greater catalytic efficiency for sulfide oxidations by $\mathrm{H}_{2} \mathrm{O}_{2}$ in the presence of strong acid, whereas the molybdenum complexes lead to a higher rate of sulfoxidation without any acid. ${ }^{[80 \mathrm{a}, 83]}$ This difference in reactivity can be attributed to the differences in Lewis acidity of molybdenum and tungsten, where the harder Lewis acid, molybdenum, forms a stronger coordination bond with the dianionic peroxo moiety, thus activating it for the oxidation of a nucleophile in the absence of acid. ${ }^{[84]}$
Polyoxomolybdenum and polyoxotungsten were found to be very efficient catalysts for the oxidation of sulfides due to form oxobridged clusters in the presence of hydrogen peroxide. In recent years, the concept combination of POM anions with IL cations is regarded feasible way to afford green POM catalyst since they might possess the advantages of both IL and POM in the same material, which has been investigated quite intensively. In this case, Zhao et al. developed a heterogeneous process for selective oxidation of sulfides with hydrogen peroxide, catalyzed by alky-tethered imidazolium IL-based polyoxomolybdenum salt catalysts. The results showed that the process almost exclusively produces sulfoxide at room temperature within a very short time of 0.5 h ; while sulfone can be selectively obtained at a higher temperature of $45{ }^{\circ} \mathrm{C}$ with excess hydrogen peroxide. ${ }^{[85]}$

## Chapter 1

### 1.4 Objective

Developing green chemistry methodologies is one of the main themes of modern synthetic chemistry. ILs have received great attention as environmentally benign solvents to replace volatile organic solvents in a wide variety of chemical reactions. The main objective of this work was to develop a cheap, environmental benign and reusable metal containing ILs or a green system for oxidation reactions.
In a first study, functional ILs containing imidazolium cations with Lewis acidic group can be used as green organocatalysts. Based on our pervious work, perrhenates which is the decomposition products of well-examined epoxidaton catalysts such as MTO should be the best candidate for synthesizing functional ILs. Therefore, a series of imidazolium-based ILs containing perrhenate anions were synthesized and used as solvents as well as catalysts for epoxidation of olefin and sulfoxidation. In addition, theoretical studies were also performed to better study the reaction mechanism of the catalytic reaction.

In a second study, in order to save the cost the metal-free ILs with weakly coordinating anions were synthesized and applied for the sulfoxidation. Then catalysis tests are conducted as well. This is especially interesting as no ILs system without any catalyst for sulfoxidation has been reported so far.

In a third study, development of transition metal catalysts in ionic liquids should be established in order to obtain the green and recycle system. The Schiff-base complexes of methyltrioxorhenium (VII) and polyoxometalates were used as catalysts for sulfoxidation and epoxidation in ILs.

### 2.1 Introduction

Although the compound class of (room temperature) ionic liquids, henceforth denoted as (RT)ILs, has been known since the middle of the 20th century, ${ }^{[1]}$ research on ILs has experienced an extraordinary growth during the last decade. ${ }^{[2]}$ Thus far, more than 40,000 research articles have been published on ionic liquids. ${ }^{[3]}$ Above all, their unique chemical and physical properties such as low miscibility with non-polar, organic solvents, low volatility, low flash point, thermal stability, high polarity, and at least in several cases, low toxicity ${ }^{[4]}$ render ILs attractive and "green" alternatives to organic solvents. ${ }^{[5]}$ Pioneering contributions of the groups of Rogers, ${ }^{[6]}$ Wasserscheid, ${ }^{[7]}$ Seddon, ${ }^{[8]}$ Welton, ${ }^{[9]}$ Dupont, ${ }^{[10]}$ among many others ${ }^{[11]}$ to the studies of SILP ${ }^{[12]}$ (Supported Ionic Liquid Phase) as reaction media for two-phase catalyzed reactions have made the catalytic application of ILs a prominent research area. ${ }^{[13]}$ In several cases, ILs have already found applications as solvents for extractants in industrial catalytic syntheses, ${ }^{[14]}$ such as the BASF-BASIL process. ${ }^{[15]}$ However, they also exhibit a templating effect in the synthesis of inorganic materials (nanoparticles, metal oxides, metal-organic frameworks). ${ }^{[16]}$ The beneficial effect on a reaction in terms of reaction rates is ascribed to a low degree of interactions (e.g. solvent cages) with the dissolved molecules. Recently, many groups focused on the functionalization of ILs, in particular those that contain imidazolium cations with Lewis acidic or basic groups, which can act as organocatalysts. ${ }^{[17]}$ Among many catalyzed processes that have been performed in ionic liquids are epoxidation reactions. ${ }^{[18]}$ The original purpose of applying ILs to this reaction was for facile
procduct/catalyst separation, which indeed could be achieved more easily in several cases than in the orginal processes. In addition, it was observed that ILs greatly affected the activity of the epoxidation catalysts, thereby leading to very active systems in several cases. ${ }^{[19]}$ Surprisingly, some typically catalytically inactive inorganic compounds, such as perrhenates (the usual decomposition products of well-examined epoxidation catalysts, such as methyltrioxorhenium (MTO)), ${ }^{[20-22]}$ displayed activity in olefin epoxidation, when applied as anions of ILs, thus showing very good yields of the epoxides and reusability of the IL. These observations led to the study reported herein. The activation of hydrogen peroxide by perrhenate, which was enabled solely by the ionic liquids environment, is to the best of our knowledge, reported for the first time. This new mode of activation allows for easy epoxidation of olefins.

### 2.2 Results and discussion

### 2.2.1 Epoxidation in perrhenate-containing ILs

Several perrhenate-containing ILs of the general formula $\left[\mathrm{C}_{\mathrm{n}} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]\left(\mathrm{C}_{\mathrm{n}} \mathrm{mim}=\right.$ 1- $\mathrm{C}_{\mathrm{n}} \mathrm{H}_{\mathrm{n}+1}$-3-methylimidazolium, $\mathrm{C}_{\mathrm{n}}=$ butyl $\left(\mathrm{C}_{4}\right)$, octyl $\left(\mathrm{C}_{8}\right)$, dodecyl $\left(\mathrm{C}_{12}\right)$ ) were synthesized and used to study the epoxidation of cyclooctene with different oxidants: $\mathrm{H}_{2} \mathrm{O}_{2}$, urea hydrogen peroxide (UHP) and tert-butyl hydroperoxide (TBHP) (Scheme 1).

Scheme 1. Olefin epoxidation in ionic liquids with the perrhenate anion.
Equimolar amounts of the IL and cyclooctene, as well as 2.5 equivalents of the oxidant, were mixed together at room temperature, thus giving a three-phase medium, which as heated at 70 ${ }^{\circ} \mathrm{C}$ for 4 h under vigorous stirring. After the reaction had been completed, the epoxide was dissolved in the IL, giving a two-phase medium IL + Product/water $+\mathrm{H}_{2} \mathrm{O}_{2}$. The epoxide was extracted with $n$-hexane ( $5 \times 1 \mathrm{~mL}$ ) and the yield of the epoxide was determined by GC. Nearly quantitative cyclooctene oxide was obtained when aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ is used as oxidant (see Table 1, Entry 1).

Table 1. Effect of oxidants on the yield of cyclooctene oxide (in percent) in imidazolium-based ILs with $\left[\mathrm{ReO}_{4}\right]^{-}$as anion.

| Entry | IL | Oxidation agent |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathrm{H}_{2} \mathrm{O}_{2} / \mathrm{H}_{2} \mathrm{O}$ | UHP | TBHP |
| 1 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ | 99 | 42 | 5 |
| 2 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ | 99 | 66 | 6 |
| 3 | $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ | 99 | 80 | 5 |

Reaction conditions: 1 mmol IL, 1 mmol cyclooctene, 2.5 mmol oxidation agent, 4 h reaction time, $70{ }^{\circ} \mathrm{C}$.
However, with UHP, yields are lower, and with TBHP, no significant yield of epoxide was obtained. In the case of UHP, the yield of cyclooctene oxide was higher when the alkyl moiety at the imidazolium cation is longer. This effect can be attributed to the increased solubility of the oxidizing agent in $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ (Entry 3). Other substrates, such as cyclohexene, styrene and 1-octene show good conversions in $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ with UHP as oxidant (see Table 2). However, the solubility of UHP in $\left[\mathrm{C}_{12} \mathrm{mim}^{2}\right]\left[\mathrm{ReO}_{4}\right]$ rendered the recycling of the IL more difficult than with hydrogen peroxide.

Table 2. Epoxidation of various olefins in $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ and UHP as oxidation agent. In all cases, the conversion of the olefins are equal to the epoxide yields, i.e. the selectivity is in each case $100 \%$.

| Entry | Substrate | Product | Yield (\%) |
| :---: | :---: | :---: | :---: |
| 1 | cyclooctene | cyclooctene oxide | 80 |
| 2 | cyclohexene | cyclohexene oxide | 63 |
| 3 | styrene | epoxystyrene | 37 |
| 4 | 1-methyl hexane | 1-methyl cyclohexane-2-on | 59 |
| 5 | 1 -octene | 1-octene oxide | 15 |

These promising findings of new peroxide chemistry were a motivation to further experimentally examine whether the addition of catalytic amounts of perrhenate to standard ILs with different polarities, such as $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ and $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$, would also lead to cyclooctene epoxidation (Table 3). Notably, different cation with $\left[\mathrm{ReO}_{4}\right]^{-}$had a tremendous effect on the activity. Whereas $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ does not provide a significant yield of the epoxide, with potassium perrhenate, yields of up to $53 \%$ (Table 3, entry 2) can be achieved. When the concentration of perrhenate is decreased to $10 \mathrm{~mol} \%$ (relative to the substrate), the activity also drops notably (Table 3, entry 3). From Table 3, it is clear that ammonium ions inhibit the epoxidation of an olefin. Similarly to peroxides, these cations interact with $\left[\mathrm{ReO}_{4}\right]^{-}$and / or the IL ions. Presumably, this interaction causes the inactivity of $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ (Table 3, entries 4 and 5), whereas $\mathrm{K}^{+}$ions behave very differently (Table 3, entries 2 and 3). This comparison also highlights the role of the IL as an environment, which is able to dissolve polar species, such as perrhenate salts, without the need to include a protic solvent shell (e.g., water; Table 3, entry 8) which would disturb the perrhenate-peroxide complexation. This argument allows a rationalizing of why perrhenates are inactive in aqueous medium, where the hydration "shell"
passivates the complex.

Table 3. Yields of cyclooctene oxide for various perrhenate concentrations (PC).

| Entry | Solvent | Perrhenate salt | PC [mol \%] | Yield [\%] |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | - | - | 13 |
| 2 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{KReO}_{4}$ | 100 | 53 |
| 3 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{KReO}_{4}$ | 10 | 10 |
| 4 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | 100 | 17 |
| 5 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | 10 | 5 |
| 6 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$ | $\mathrm{KReO}_{4}$ | 100 | 3 |
| 7 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$ | $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | 100 | 7 |
| 8 | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | 100 | 8 |

Reaction conditions: $0.5 \mathrm{ml} \mathrm{IL}, 1 \mathrm{mmol}$ cyclooctene, $2.5 \mathrm{mmol} \mathrm{H} \mathrm{H}_{2} \mathrm{O}_{2}$ ( $50 \%$ solution in water), reaction time $4 \mathrm{~h}, 70^{\circ} \mathrm{C}$.

By comparing the use of two ILs, $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$ and $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ as solvents (Entries 2, 4, 6 and 7), we can clearly conclude that the solubility of the perrhenate salt in the respective IL has a significant influence on the activity towards epoxidation. A more polar IL like $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ will facilitate the solubility of the perrhenate salt, leading to formation of hydrogen bonds between perrhenate and $\mathrm{H}_{2} \mathrm{O}_{2}$. A reciprocal observation is made with [ $\left.\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right.$ ], wherein $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and $\mathrm{KReO}_{4}$ are entirely insoluble, leading to yields of $7 \%$ and $3 \%$, respectively.
Recycling experiments were carried out on samples of the $\mathrm{IL}\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ (Figure 1). Constant yields of $98-99 \%$ were obtained for at least 8 runs, which demonstrates the high stability of the IL under oxidative conditions, thus rendering it a good candidate for efficient olefin epoxidation.

Figure 1. Yields of cyclooctene oxide after eight reaction runs in $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$.

### 2.2.2 Mechanistic considerations of the activation of $\mathbf{H}_{2} \mathrm{O}_{2}$

The reactivity of the perrhenate-containing IL is intriguing. In contrast, by using [ $\left.\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ without the addition of a metal oxide, cyclooctene epoxide is obtained in $13 \%$ yield (Table 2,

Entry 1), thus pointing to the pivotal role of perrhenate in the conversion of the olefin into the corresponding epoxide. However, this fundamental-yet surprising-activity of $\left[\mathrm{BF}_{4}\right]^{-}$can be rationalized by the formation of hydrogen bonds between $\left[\mathrm{BF}_{4}\right]^{-}$with hydroxides. ${ }^{\left[9 b,{ }^{23]}\right.} \mathrm{To}$ verify whether the $\left[\mathrm{BF}_{4}\right]^{-}$anion is responsible for the activation of hydrogen peroxide, or whether they even react with the peroxide or water, in situ ${ }^{19} \mathrm{~F}$-NMR spectra, $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ (see Figure 2), were recorded in the presence of perrhenate and hydrogen peroxide.

Figure 2. ${ }^{19} \mathrm{~F}$-NMR Spectra ( $200-200 \mathrm{ppm}$ ) of $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ at $70{ }^{\circ} \mathrm{C}$ : without $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{~A})$, with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and $\mathrm{H}_{2} \mathrm{O}_{2}$ after 30 min . (B) and $90 \mathrm{~min}(\mathrm{C})$.

Notably, no change in the fluorine signals during epoxidation were observed, thus showing that $\left[\mathrm{BF}_{4}\right]^{-}$anion did not react with $\mathrm{H}_{2} \mathrm{O}_{2}$ or was hydrolyzed by water. Therefore, we can conclude that the $\left[\mathrm{BF}_{4}\right]^{-}$anion is not (or only to a minor degree) responsible for the activation in the presence of $\left[\mathrm{ReO}_{4}\right]^{-}$, as also corroborated by vibrational spectroscopy.
Welton and co-workers reported the formation of hydrogen bonds between the IL anions and water molecules. ${ }^{[24]}$ Mele et al. observed weak H bonding of the imidazolium cation with water. ${ }^{[25]}$ Hence, in Table 2, entry $1, \mathrm{H}_{2} \mathrm{O}_{2}$ is presumably associated with the IL anion. Hydrogen bonds to the cation probably do not form in the presence of a potent H -bond acceptor such as a perrhenate anion. The addition of metal-oxo complexes, such as $\left[\mathrm{ReO}_{4}\right]^{-}$, accelerates the reaction, presumably through the formation of $\mathrm{O}_{3} \mathrm{Re}-\mathrm{O} \cdots \mathrm{H}-\mathrm{O}-\mathrm{OH}$ species, which activate the peroxide and hence, enable epoxidation. Seemingly, metal-oxide-mediated olefin epoxidation in ILs follows a different reaction mechanism to that with the usually metal catalysts, ${ }^{[11]}$ in which (hydro) peroxo ligands act as catalytically active species in transferring an oxo moiety to the olefin. ${ }^{[26]}$ The activation of peroxides with the carbonate anion and the
subsequent epoxidation of olefins were reported by Yao and Richardson. ${ }^{[27]}$ However, their reactions were performed in water and, thus, the substrates had to contain functional groups (carboxylate, sulfonate, ester) that would render them soluble; hence, the reactions of simple olefins were not undertaken. The mechanism has also not been examined in detail. Therefore, to shine some light onto the activation of peroxide with perrhenate, the reaction mechanism was also examined by DFT calculation.

### 2.2.3 Spetroscopic and DFT studies of the activation of $\mathbf{H}_{2} \mathrm{O}_{2}$ with perrhenate and subsequent epoxidation

Recent publications presented elaborate schemes for modeling ILs. ${ }^{[28-29]}$ The scope of the calculations reported herein was to elucidate and support the proposed catalytic mechanisms, in particular in terms of the trends in crucial activation barriers. Therefore, as first approximation, we refrained from directly including the effects of ILs that are often described by using molecular modeling approaches. We relied on ILs to provide a reaction cavity and we assumed that gas phase models correctly helped to identify trends. Thus, the absolute values of barrier heights should be taken with caution. Three complexes from which the oxidation may start were considered (Scheme 2): that is, encounter complex 1 between hydrogen peroxide and $\left[\mathrm{ReO}_{4}\right]^{-}$, the hydroxo-hydroperoxo rhenium species $\mathbf{3}$, and the bishydroxo-peroxo complex 5. ${ }^{[30]}$

Scheme 2. Calculated equilibrium structures for the reaction of $\left[\mathrm{ReO}_{4}\right]^{-}$with $\mathrm{H}_{2} \mathrm{O}_{2}$ including the transition states (ts). All of the complexes are monoanions. These dashed lines indicate hydrogen bonds, thick dashed lines bonds to be broken or formed in a reaction step. Free reaction energies ( $\mathrm{kJ} \mathrm{mol}^{-1}$ ) relative to $\mathbf{1}$, activation barriers relative to the preceding initial state. Color coding of the atomic spheres: Re green, large; O red; H white, small.

Before exploring the actual mechanism, it is important to identify active species that are formed with peroxide in the IL. Therefore, the reactions were monitored via in situ IR and Raman spectroscopy. Upon addition of the oxidant, the asymmetric stretching vibration splits
in both the Raman and IR spectra (Figure 3, spectrum a). Point group analysis shows that this is consistent with a lowering of the local symmetry of $\left[\mathrm{ReO}_{4}\right]^{-}$from $\mathrm{T}_{d}$ to $\mathrm{C}_{2 v}$.

These changes can be assigned to a distortion of the local symmetry of the anion by weak coordination, for example, hydrogen bonds. This assignment is supported by calculated vibrational spectra of the key intermediates (1, $\mathbf{3}$ and 5; Figure 3). Indeed, in the IR spectra, the experimentally observed splitting ( $890-920 \mathrm{~cm}^{-1}$; Figure 3, spectrum a) of the former asymmetric stretching mode of the pure ionic liquids, which is found at about $900 \mathrm{~cm}^{-1}$ (see Figure 3), ${ }^{[1]]}$ is also reflected in the simulated spectra (Figure 4).

Figure 3. Raman and mid-IR spectra of $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ ( $\mathrm{Re}=\mathrm{O}$ asymmetric stretch vibration) after peroxide addition. Calculated: encounter complex 1, hydroxo-hydroperoxo complex 3, and peroxo complex 5; a: measured, and $\mathbf{b}$ : 2nd derivative of the spectra. Peak broadenings indicated as horizontal bars (see text).

For structure 1, a small splitting is calculated, with three peaks within the range $865-910 \mathrm{~cm}^{-1}$, where as the ligands on the metal center of structures $\mathbf{3}$ and $\mathbf{5}$ induce a significant larger broadening of the spectra (3: $840-985 \mathrm{~cm}^{-1} ; \mathbf{5}: 875-990 \mathrm{~cm}^{-1}$ ). Both the shift and splitting of this band, as observed experimentally (spectrum a), are best reproduced by the simulated for complex 1. Thus, from IR data, structure 1 is expected to be predominantly formed. In the Raman spectra, the asymmetric stretching mode of the pure ionic liquid at about $916 \mathrm{~cm}^{-1}$ (see

Figure 3), is broadened to $885-930 \mathrm{~cm}^{-1}$ (Figure 4, spectrum a). Again, this finding is supported by the calculated spectrum of encounter complex 1, which exhibits a broadening to $875-930 \mathrm{~cm}^{-1}$. The splitting patterns in the Raman spectra of $\mathbf{3}$ and $\mathbf{5}$ are also significantly broadened (3: 840-985 $\mathrm{cm}^{-1} ; \mathbf{5}: 875-990 \mathrm{~cm}^{-1}$ ). The calculated spectrum of structure $\mathbf{1}$ has a slightly different peak pattern to the second derivative of the experimental spectrum (spectrum b, extended view). The simulated IR and Raman spectra of structures $\mathbf{3}$ and $\mathbf{5}$ show an additional peak at about $980 \mathrm{~cm}^{-1}$, which is assigned to the hydroxyl groups but is not observed in experimentally, thus corroborating the dominance of structure $\mathbf{1}$ in the reaction. Far-IR measurements do not indicate any additional Re-O vibrations, excluding the formation of rhenium-peroxo species.

Figure 4. Comparison of calculated and mearsured Raman spectra of the pure ionic liquid: $\left[\mathrm{ReO}_{4}\right]^{-}$ calculated, $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ measured. The peak at $1020 \mathrm{~cm}^{-1}$ in the experimental spectrum results from the ${\left[C_{8} \mathrm{mim}\right.}^{+}$counter ion.

Thus, structure 1 can be safely addressed as the predominant equilibrium structure. The formation of the encounter complex $\mathbf{1}$ is calculated to be exothermic by $-20 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Scheme 2), owing to the newly formed H bonds. Compound $\mathbf{1}$ can be considered as an initial state of all reaction pathways. Thus, all of the free reaction energies shown are given relative to structure 1. A barrier of $112 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (2_ts) has to be overcome to arrive at the endothermic hydroxo-hydroperoxo complex $\mathbf{3}\left(82 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$. The strongly endothermic peroxo complex 5
$\left(156 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ is reachable via a barrier of $79 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (4_ts). Hence, these latter alternatives to structure $\mathbf{1}$ are both thermodynamically and kinetically disfavored. These computational results, together with the findings on the vibrational spectra, indicate that the equilibrium of the ionic liquid and hydrogen peroxide will be predominantly shifted towards complex $\mathbf{1}$. As a consequence, during the reaction, $\left[\mathrm{ReO}_{4}\right]^{-}$can be assumed to be coordinated by $\mathrm{H}_{2} \mathrm{O}_{2}$ through H bonds, thus activating the peroxide bond and making it susceptible to attack by an olefin. In contrast to MTO, the stable delocalized electronic structure of perrhenate implies a chemical inertness that requires a significant amount of energy to be disturbed, for example, by inserting $\mathrm{H}_{2} \mathrm{O}_{2}$ to yield structures $\mathbf{3}$ and $\mathbf{5}$.
Further computational efforts addressed the question whether a single perrhenate moiety or peroxide-bridged agglomerates of such anions may act as active species (see Figure 5).

M1

M2: symmetric

M2: bridged

D1
D2

Figure 5. Possible perrhenate-peroxide complexes, either mono- (M) or dimers (D), as alternatives to M1 (structure $\mathbf{1}$ of the article).

Simulated Raman spectra did not exclude such agglomerates (see Figure 6). The formation of such structures will depend on the size and the content of the reaction cavity provided by the IL, specifically on the size of the counterion. Mono-perrhenates that contain two peroxide moieties are also conceivable as active species, thus enhancing the possibility for epoxidation.

Figure 6. Calculated Raman spectra of various systems in comparison with experimental spectra of $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$.

Although our spectroscopic studies show that the equilibrium is shifted almost completely towards complex 1, epoxidation might involve one of the minor intermediates. Therefore, we examined various plausible transition states (ts). Accordingly, among all of the reaction channels studied, the rate-limiting barrier (relative to structure 1) was by far the lowest for direct oxidation by complex 1 (see Figure 7).

## Chapter 2

Figure 7. Alternative reaction pathways and their activation barriers. Values given are Gibbs free energies (in $\mathrm{kJ} \mathrm{mol}^{-1}$ ) relative to the intermediate 1. Activation barriers in parentheses are relative to the preceding intermediate.

Transition state 7_ts lies $171 \mathrm{~kJ} \mathrm{~mol}^{-1}$ above the preceding intermediate state (IS) 6 (Scheme 3). A second hydrogen bond does not necessarily have to form to the same $\left[\mathrm{ReO}_{4}\right]^{-}$unit.

Scheme 3. Calculated reaction pathway of direct epoxidation through the H -bonded complex $\mathbf{1}$. Gibbs free energies (in $\mathrm{kJ} \mathrm{mol}^{-1}$ ) are relative to the separated substrates, $\left[\mathrm{ReO}_{4}\right]^{-}$and $\mathrm{H}_{2} \mathrm{O}_{2}$. All of the complexes are mono-anions. Free energies calculated as in Scheme 2. Color coding of the atomic spheres: C black, small; the rest as in Scheme 2.

We were unable to identify an alternative structure for product $\mathbf{8}$ that involved a water molecule bound through H bonds to the perrhenate anion. A water ligand, which coordinated at the perrhenate through its oxygen atom, analogous to structures that have previously been found in MTO chemisty, ${ }^{[32-33]}$ immediately reorients to form structure 8. The barrier of the corresponding back reaction was calculated to be $355 \mathrm{~kJ} \mathrm{~mol}^{-1}$; hence, the reverse step is highly unlikely. Direct insertion, starting from structure 1, encounters a notably higher barrier ( $256 \mathrm{~kJ} \mathrm{~mol}^{-1}$; see Figure 7). In agreement with experimental findings that identify structure $\mathbf{1}$ as the prevailing species, alternative epoxidation pathways, starting from structures $\mathbf{3}$ or $\mathbf{5}$, are far less likely (Scheme 2). The barriers of such alternative oxygen-transfer pathways relative to structure $\mathbf{1}$, that is, neglecting the energy change owing to coordination of the olefin, are at least $254 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (see Figure 7). To elucidate the origin atom in the epoxide product, the epoxidation of cyclooctene was repeated using ${ }^{17} \mathrm{O}$-labeled $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ and $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant. After work up and product isolation, the recorded ${ }^{17} \mathrm{O}$-NMR spectrum of cyclooctene oxide does not show any signal, even after 24 h of acquisition time. This result clearly excludes the formation of Re-hydroperoxo (3) or Re-peroxo (5) species, that is, a transfer of oxo ligands from Re onto the olefin. Thus, the oxygen has to originate from $\mathrm{H}_{2} \mathrm{O}_{2}$, without prior direct coordination at the metal center, thus suggesting the pathway starting from structure 1.

Thus far, we have only discussed mechanistic aspects only with regard to $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant. It is the question, which effects are responsible for the poor epoxide yields when using UHP and TBHP as oxidants (Table 1). Analogous to structure $\mathbf{1}$ with oxidant $\mathrm{H}_{2} \mathrm{O}_{2}$ (Scheme 2), we examined the H -bonded encounter complexes ( $\mathbf{1 a}$ and $\mathbf{1 b}$ ) of perrhenate and the oxidants UHP and TBHP, respectively (Figure 4). Oxidant UHP, viewed as adduct of $\mathrm{H}_{2} \mathrm{O}_{2}$ and urea (see 1a), exhibits H bonds between the hydroxyl groups of $\mathrm{H}_{2} \mathrm{O}_{2}$ and the carbonyl and amino
functions of urea. ${ }^{[34]}$ In structure 1b, the tert-butyl group of TBHP shields the oxygen center to be transferred. In contrast to structure 1, both structures $\mathbf{1 a}$ and $\mathbf{1 b}$ can only form a single H -bond to perrhenate (Figure 8).

1a

1b

Figure 8. Encounter complexes of $\left[\mathrm{ReO}_{4}\right]^{-}$with UHP (1a) and TBHP (1b).
Color coding of the atomic spheres: N blue, small; the rest as in Scheme 3.
According to the calculated activation barriers, relative to the corresponding ISs (1, 1a or 1b; Scheme 3, Figure 8), direct epoxidation with UHP (7a_ts, $173 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ) is favored over the reactions of alternative oxidants $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right.$ : 7_ts, $192 \mathrm{~kJ} \mathrm{~mol}^{-1}$; TBHP: 7b_ts, $189 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). Thus, the electronic activation of the peroxide does not correlate with the measured trend of yields (Table 1).
Notably, the yields are affected by: 1) steric shielding of the activated center, 2) competition between the substrates, and 3) the thermodynamic driving force, in particular the activation barrier of the back reaction. Whilst the calculated free reaction energies for the overall reaction with $\mathrm{H}_{2} \mathrm{O}_{2}\left(-192 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ and $\mathrm{UHP}\left(-190 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ are similar, the reaction is far less exothermic with TBHP $\left(-170 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$. Furthermore, the tert-butyl group TBHP that is coordinated to the perrhenate anion shields the oxygen center, thus (together with the slightly lower reaction free energy) rationalizing the poor yields (Table 1). Other factors may contribute to the differing activities of UHP and $\mathrm{H}_{2} \mathrm{O}_{2}$. For instance, urea does not need to stay close to the complex of perrhenate and $\mathrm{H}_{2} \mathrm{O}_{2}$, but may coordinate to another perrhenate ion. According to calculated energies of the H bonds between perrhenate and various substrates, urea ( $34 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ) binds more strongly to perrhenate than $\mathrm{H}_{2} \mathrm{O}_{2}\left(20 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$, whilst water binds weakest ( $8 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). System $\mathbf{1}\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ contains notable amounts of water because the oxidant is available in aqueous solution, whereas system 1a (UHP) only incorporates urea and $\mathrm{H}_{2} \mathrm{O}_{2}$. Thus, the epoxidation yields can be rationalized as the result of competition between forming a perrhenate complex with either urea or $\mathrm{H}_{2} \mathrm{O}_{2}$. Notably, ammonium ions almost completely suppressthe reaction (Table 3) because they form very strong H bonds with perrhenate anions ( $404 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ).
The cations of the IL, not accounted for in our simple models, are obviously not innocent
(Table 1). Despite its simplicity, this computational approach demonstrates the feasibility of the discussed mechanism. Clearly, more elaborate modeling of the environment that is set up by the IL will be desirable. With such more realistic modeling, the calculated activation barriers would be expected to be lower. Because the high activation barrier of $173 \mathrm{~kJ} \mathrm{~mol}^{-1}$ is at odds with the good observed yields (at least $50 \%$ ), the rate limiting step has been recalculated with the experimentally used substrate (cyclooctene), which is known to be more easily epoxidized than the model olefin (ethene). ${ }^{[35]}$ The resulting activation barrier of 143 kJ $\mathrm{mol}^{-1}$ demonstrates better agreement between the chosen computational model and the experimental data, as well as the far better reactivity of cyclooctene in comparison to ethene. Assuming a first-order reaction and a pre-exponential factor of $1013 \mathrm{~s}^{-1}$, we estimate a barrier of about $110 \mathrm{~kJ} \mathrm{~mol}^{-1}$ based on the observed $50 \%$ yield after 4 h .

### 2.3 Conclusion

A new synthetic concept which is based on the solvent effect of ionic liquids on polar compounds, such as perrhenate salts is presented. NMR, IR, and Raman spectroscopy, as well as by DFT studies, indicate that simple anionic metal-oxo complexes are able to activate hydrogen peroxide through hydrogen-bonding interactions, thus enabling olefin epoxidation through an outer-sphere mechanism, which does not involve the Re center. This method was shown to be very efficient, even with catalytic amounts of metal salts, which are easily separated from the product and reused without loss of activity. This reaction type opens up new possibilities for the epoxidation of olefins with compounds that are very stable, readily accessible, and cheap. These compounds have several advantages over the meanwhile commonly used, yet expensive molecular $\mathrm{Re}, \mathrm{Mo}, \mathrm{Ti}$, and Mn compounds, which are expensive and often quite sophisticated. Further studies of this reaction system are worthwhile, particularly in view of affording longer-term stability and performance in the epoxidation of cyclooctene.

### 2.4 Experimental section

### 2.4.1 General

All syntheses and catalytic reaction were carried out in air. 1-methylimidazole, 1-bromobutyl, 1-bromooctyl, 1-bromododecyl, fluoroboric acid (50\%), hydrogen peroxide ( $50 \%$ in water), $n$-hexane, acetonitrile, and ethyl acetate were purchased from Acros Organics. NaOH pellets were purchased from J. T. Baker. Cyclooctene ( $95 \%$ ), tert-butyl hydroperoxide 5.0-6.0 M
solution in decane, Amberlite IRA-400 (OH), and acetone were purchased from Sigma-Aldrich. ${ }^{17}$ O-enriched water ( 10 wt. \%) was purchased from Deutero GmbH. All chemicals were used as received without further purification.
Microanalyses of the obtained products were performed in the Mikroanalytisches Labor of the Technische Universität München in Garching. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{17} \mathrm{O}$ NMR spectra were recorded in $\mathrm{CDCl}_{3}$ with a $400-\mathrm{MHz}$ Bruker Avance DPX-400 spectrometer. In-situ Mid-IR spectra were recorded with Mettler Toledo ReactIRTM, ex-situ spectra were measured on a Varian IR FT670 equipped with an ATR cell (diamond crystal). Raman spectra were recorded on a Bio-Rad FTS-60A. Thermogravimetry coupled with mass spectroscopy (TG-MS) was conducted utilizing a Netzsch TG209 system; typically 10 mg of each sample were heated from $25^{\circ} \mathrm{C}$ to $1000{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Differential Scanning Calorimetry (DSC) was performed on a Q 2000 series DSC instrument, where 2 mg of each sample were heated from $-100{ }^{\circ} \mathrm{C}$ to $150{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Density was measured by an Anton Paar DMA4500 densimeter. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II.

### 2.4.2 Synthesis of perrhenate-based ILs

The original synthesis of the perrhenates involved a mixture of imidazolium bromide and $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ in acetone, which was stirred for 48 h at room temperature and subsequently worked up. Elemental analysis showed that a significant amount of the bromide was present in the ionic liquid after purification. Because the purity of the new ILs has a dramatic effect on the epoxidation of olefins, a new strategy was used for the synthesis of the IL perrhenates, which involved the exchange of bromide by hydroxide on an ion exchange resin and subsequent addition of $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ and stirring at $70^{\circ} \mathrm{C}$ for 24 h . The only byproducts are ammonia and water, which can easily be removed in vacuo at elevated temperatures. The ionic liquids were characterized by FT-IR, Raman, ${ }^{1} \mathrm{H}$-, ${ }^{13} \mathrm{C}$-, ${ }^{17} \mathrm{O}-\mathrm{NMR}$ spectroscopy and elemental analysis. In Addition, physical data such as density, melting point and decomposition temperature were determined. According to differential scanning calorimetry (DSC) data, the compounds $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ and $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ were liquid and contain a glass-transition temperature below room temperature having a glass transition temperature below room temperature. Owning to its high molecular mass, $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ shows a melting point at $48^{\circ} \mathrm{C}$. Thermogravimetric analysis (TGA) data indicate that all ionic liquids show negligible volatility and high thermal stability with a decomposition onset temperature
near to $400^{\circ} \mathrm{C}$.
Equimolar amount of alkyl bromide and 1-methylimidazole ( 0.5 mol ) were heated for 1 h at $40^{\circ} \mathrm{C}$ in THF ( 40 ml ). Afterwards, the mixture was heated at reflux for 24 h . After cooling to room temperature, a mixture of EtOAc and $\mathrm{MeCN}(40 \mathrm{~mL}, 3: 1 \mathrm{v} / \mathrm{v})$ were added and the mixture was heated at reflux for 1 h to afford the pure product after drying at $80^{\circ} \mathrm{C}$ under high vacuum for 8 h .

Preparation of 3-alkyl-1-methyl imidazolium perrhenate: A solution of 3-alkyl-1-methyl imidazolium bromide ( 0.08 mmol ) in water $(10 \mathrm{~mL})$ was slowly added onto the ion-exchange resin (PH 7). The product was slowly washed off the column with water until PH value of the eluent remained at 7 , thus affording the desired product ( $\mathrm{c}=0.26 \mathrm{~mol} \mathrm{~L}^{-1}$ ). Subsequently, $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ (1.2 equiv) was added and the solution was heated to $70{ }^{\circ} \mathrm{C}$ for 24 h , followed by the complete removal of the residual water under reduced pressure. Excess $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ was removed by extraction of the ionic liquid with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(30 \mathrm{~mL})$ to afford the pure product after removal of the solvent under reduced pressure ( $98 \%$ yield).

3-butyl-1-methyl-1H-imidazolium perrhenate
$\mathrm{C}_{8} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{O}_{4} \mathrm{Re}(389.42),{ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right.$, r.t.): $\delta=8.92(1 \mathrm{H}, \mathrm{s}), 7.32(1 \mathrm{H}, \mathrm{d}), 7.34$ $(1 \mathrm{H}, \mathrm{d}), 4.30(2 \mathrm{H}, \mathrm{t}), 3.68(3 \mathrm{H}, \mathrm{s}), 1.75(2 \mathrm{H}, \mathrm{q}), 1.26-1.17(2 \mathrm{H}, \mathrm{m}), 0.79 \mathrm{ppm}(3 \mathrm{H}, \mathrm{t})$; ${ }^{13} \mathrm{C}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right.$, r.t.): $\delta=135.9,123.6,122.3,49.7,36.3,31.7,19.1,13.2 \mathrm{ppm}$; IR (ATR, diamond crystal, neat): $v=900$ (Re=O asym.), $916 \mathrm{~cm}^{-1}$ ( $\mathrm{Re}=0$ sym.); elemental analysis calc. ### 2.4.3 Preparation of the ${ }^{17} \mathrm{O}$-labeled ILs

${ }^{17} \mathrm{O}$-labeled water ( $100 \mu \mathrm{~L}, 10$ atom $\%$ ) was added to 1,3 -methyl-octyl-imidazolium perrhenate ( 3.7 mmol ) and the solution was stirred at room temperature for 16 h . Afterwards, water was removed under reduced pressure.

### 2.4.4 Oxidation of cyclooctene to cyclooctene oxide in ILs

The ionic liquid ( 1 mmol ) was placed in a round bottom flask equipped with a magnetic bar, followed by the addition of substrate ( 1 mmol ). Finally, the oxidant $(2.5 \mathrm{mmol})$ was added and the reaction mixture was heated up to $70^{\circ} \mathrm{C}$ for 4 h . Afterwards, the epoxide was extracted with $n$-hexane ( $5 \times 1 \mathrm{ml}$ ) and a solution of epoxide in $n$-hexane ( $100 \mu \mathrm{~L}$ ) was mixed with $1000 \mu \mathrm{~L}$ of internal standard and measured by means of GC.

### 2.4.5 Computational details

All electronic structure calculations were carried out with the program package Gaussian 0336 with the hybrid DFT functional B3LYP. ${ }^{[37]}$ For the description of rhenium, we employed the MWB-60 energy-averaged Stuttgart/Dresden pseudopotential; ${ }^{[38]}$ all other atoms were represented by the $6-311+G(d, p)^{[39]}$ basis set. In general, we invoked simple models that focus on perrhenate. These models did not account for the environment provided by the ionic liquid; in particular, all effects of the 1R-3-methylimidazolium ([RMIM] $]^{+}$) counter ions ( $\mathrm{R}=$ butyl, octyl, or dodecyl) were neglected. This model approach assumes the environment provided by the ionic liquid (IL) will not prevent the formation of weak hydrogen (H) bonds between a perrhenate anion and peroxide (typically about $1.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). These H bonds are not stable in a common organic solvent due to strong coordination of the substrate by a solvent. Such solvent effects are assumed to be absent in an IL. $[\mathrm{RMIM}]^{+}$counter ions, known as H bond donors, ${ }^{[40]}$ are not expected to participate as H bond acceptors in the reaction mechanism, e.g. the complexation and activation of peroxides, in view of their cationic character and the complete lack of lone-pair bearing atoms. ${ }^{[41]}$

# 3 Imidazolium perrhenate ionic liquids as efficient catalysts for the selective oxidation of sulfides to sulfones 

This chapter originated from the following publication:<br>Bo Zhang, Su Li, Shuang Yue, Mirza Cokoja, Ming-Dong Zhou,<br>Shu-Liang Zang* and Fritz E. Kühn*

J. Organomet. Chem. 2013, 744, 108-122.

### 3.1 Introduction

The synthesis of sulfoxides and sulfones is of interest due to their valuable applications as intermediates during the preparation of various chemically and biologically important molecules. ${ }^{[1-7]}$ The selective oxidation of sulfides is the most straightforward method for synthesis of sulfones. A plethora of procedures are available using transition-metals such as $\mathrm{V}-,{ }^{[8]} \mathrm{Re}-,{ }^{[9]} \mathrm{Mn}-,{ }^{[10]} \mathrm{Ti}-,{ }^{[11]} \mathrm{Mo}-{ }^{[12-14]}$ and $\mathrm{W}_{-}{ }^{[15-16]}$ based catalysts for the preparation of sulfones in organic solvents. However, most of these procedures are not satisfactory due to high cost, difficult catalyst preparation and separation, and due to the formation of large volumes of toxic waste. Therefore, a high demand for the development of low cost, green, efficient and durable homogeneous catalysts for oxidation of sulfides to sulfones exists. In this respect, ionic liquids (ILs) are environmentally benign reaction media for reactions, separations, and manufacturing processes due to their favorable physical and chemical properties. ${ }^{[17-24]}$ In particular, metal-containing ILs may be particularly interesting candidates as reaction media or catalysts because of their special characteristics, such as easy preparation and separation, catalyst stability, solubility and reusability. ${ }^{[17, ~ 21, ~ 25-26] ~}$
Since more than two decades, methyltrioxorhenium (MTO) has been known to be a very efficient catalyst for the oxidation of organic compounds. ${ }^{[27-32]}$ The catalyst recycling and hence reusability of the system is, however, intrinsically difficult, since both catalyst and product are soluble in the same phase. Immobilization of MTO on heterogeneous carrier materials has been proven to be difficult as well. Notorious leaching quickly leads to significant catalyst losses in almost all examined cases. ${ }^{[33-34]}$ It is known that certain other
rhenium (VII) compounds, such as acetyl perrhenate ( $\mathrm{O}_{3} \mathrm{Re}-\mathrm{OAc}$ ) and immobilized benzyltrioxorhenium (VII), are also displaying catalytic activities under special conditions. ${ }^{[28,}$ ${ }^{35-37]}$ Furthermore, perrhenate itself has so far only been known as a mediocre catalyst for the reaction of diols to olefins, ${ }^{[38-39]}$ but it has not been applied as catalyst or initiator in the epoxidation of olefins, unlike its Re (VII) congener MTO. These results were tempting enough to extend our investigations to design perrhenate containing ionic liquids since they might possess the advantages of both of ILs and catalyst (perrhenate). Initial work in this field has been focused on the epoxidation that imidazolium perrhenate ionic liquids (IPILs) of the general type $\left[\mathrm{C}_{\mathrm{n}} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]\left(\mathrm{C}_{\mathrm{n}} \mathrm{mim}=1-\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}+1}-3\right.$-methylimidazolium; $\mathrm{n}=2(\mathbf{1}), 4$ (2), 5 (3), $6(4), 8(5), 10(6), 12(7)$, see Figure 1) are very efficient reaction media for the epoxidation of simple olefins (cyclooctene, 1-octene, styrene) using aqueous hydrogen peroxide and UHP as oxidants. ${ }^{[40]}$ Due to negligible solvent-perrhenate interactions in these ILs, $\mathrm{H}_{2} \mathrm{O}_{2}$ can form hydrogen bonds with the Re-oxo ligands, which activates $\mathrm{H}_{2} \mathrm{O}_{2}$ and makes it susceptible for epoxidation. Further research, summarized in this paper, shows that IPILs can be used in catalytic amounts for the oxidation of sulfides to sulfones with hydrogen peroxide as oxidant and conventional $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ (1-butyl-3-methylimidazolium tetrafluoroborate) ionic liquid as solvent under mild conditions.

Figure 1. Imidazolium perrhenate ILs 1-7 (IPILs).

### 3.2 Results and discussion

### 3.2.1 Characterization of the IPILs

Physical data such as density, melting point and decomposition temperature were determined (see Table 1). Compounds $\mathbf{1 - 5}$ are liquids at room temperature and a glass transition process can be detected below room temperature according to differential scanning calorimentry (DSC) data. Compounds $\mathbf{6}$ and $\mathbf{7}$ show melting points of 38.3 and $48.3^{\circ} \mathrm{C}$, respectively. The
thermogravimetric analysis (TGA) data indicate that all compounds show negligible volatility and high thermal stability with a decomposition onset temperature near $400^{\circ} \mathrm{C}$ (see Table 1).

Table 1. Physical data of ionic liquids 1-7.

| Compounds | Melting point/Glass transition <br> temperature <br> $\left[{ }^{\circ} \mathrm{C}\right]$ | Density <br> $\left[\mathrm{g} / \mathrm{cm}^{3}\right]$ | Decomposition temp. <br> onset <br> $\left[{ }^{\circ} \mathrm{C}\right]$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | -15.2 | 2.157 | 395.2 |
| $\mathbf{2}$ | -76.5 | 1.963 | 399.3 |
| $\mathbf{3}$ | -73.9 | 1.851 | 396.7 |
| $\mathbf{4}$ | -61.1 | 1.794 | 393.9 |
| $\mathbf{5}$ | 9.2 | 1.658 | 380.2 |
| $\mathbf{6}$ | 38.3 | 1.527 | 381.3 |
| $\mathbf{7}$ | 48.3 | 1.433 | 383.5 |

### 3.2.2 Influence of solvent, oxidant and catalyst

We studied the catalytic properties of IPILs 2, 5 and $\mathbf{7}$ for the oxidation of thioanisole using aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ and UHP as oxidants. For comparison, various oxidants and catalysts in different reaction media were also tested. The results are given in Table 2. Several organic solvents and ILs, such as $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$ (1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide), $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{HSO}_{4}\right]$ (1-butyl-3-methylimidazolium hydrogen sulfate) and $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{PF}_{6}\right]$ (1-butyl-3-methylimidazolium hexafluorophosphate) were applied as solvents. Oxidation of thioanisole with aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant was found to be strongly solvent dependent. When using conventional solvents, such as $n$-hexane and toluene (Entries $1-2$ ) the yield of sulfone is below $60 \%$, and the selectivity toward sulfone is less than $80 \%$, due to the low solubility of the catalyst in these solvents. Higher yields (> $60 \%$ ) were obtained in MeOH and the examined ILs as solvents, since the solvent/substrate/oxidant mixture is homogeneous (Entries 3-7). $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ (1-butyl-3-methylimidazolium tetrafluoroborate) turned out to be the best solvent providing the highest yield (96 \%) and the best selectivity (98 \%) (Entry 4). Other ILs such as [C4mim][ $\mathrm{NTf}_{2}$ ] and $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{HSO}_{4}\right]$ exhibited also high yields (Entries 5 and 6). For sake of comparison, tert-butyl hydroperoxide (TBHP) and urea hydrogen peroxide (UHP) were also used as oxidants under the same conditions. The catalytic activity decreases significantly with TBHP as oxidant (Entry 10). In the case of UHP, the low solubility appears to affect the reaction negatively, leading to a low yield (Entry 9). A blank experiment without oxidant was carried out under the same conditions and no significant oxidation was observed within 24 h , indicating that the oxygen
source in the oxidation reaction was not air (Entry 8). Based on these results, $\mathrm{H}_{2} \mathrm{O}_{2}$ appears to be superior to TBHP and UHP as oxidizing agent.

Various easily available rhenium compounds, such as $\mathrm{K}\left[\mathrm{ReO}_{4}\right]$ and $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ have been applied as catalysts in the oxidation of thioanisole with aqueous hydrogen peroxide (Entries 12 and 13). $\left[\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ and $\mathrm{K}\left[\mathrm{ReO}_{4}\right]$ provide a yield of up to $93 \%$. Compared to [ $\left.\mathrm{NH}_{4}\right]\left[\mathrm{ReO}_{4}\right]$ and $\mathrm{K}\left[\mathrm{ReO}_{4}\right]$, compound $\mathbf{2}$ exhibites a better performance for the oxidation of thioanisole (Entry 4) due to the better solubility in $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$. Besides, the more lipophilic IPILs 5 and 7 were examined as catalysts for oxidation of thioanisole. The results show that increasing the carbon chain length in the imidazolium had little effect on yield and selectivity (Entries 14 and 15). Importantly, in the absence of perrhenate, the sulfone yield decreased to mere $13 \%$. The sulfoxide yield, however, is $86 \%$ (Entry 11), which is in good accord with the method selectively oxidizing sulfides to sulfoxides in $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] .{ }^{[44]}$ This result shows that the "over-oxidation" to sulfones can only be induced by perrhenate and not by $\mathrm{BF}_{4}$. Regarding the mechanism of this reaction, it has previously been shown that $\left[\mathrm{ReO}_{4}\right]^{-}$ activates $\mathrm{H}_{2} \mathrm{O}_{2}$ via hydrogen bonds, facilitating the epoxidation of olefins. ${ }^{[40]}$ Analogously, the oxidation of sulfides to sulfones is assumed to take place through the same mechanism.

Table 2. Catalytic oxidation of thioanisole under different reaction conditions. ${ }^{[a]}$

| Entry | Solvent | Oxidant | Catalyst | Yield ${ }^{[b]}[\%]$ | Selectivity ${ }^{[b]}[\%]$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $n$-hexane | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 57 | 58 |
| 2 | Toluene | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 50 | 78 |
| 3 | MeOH | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 62 | 63 |
| 4 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 96 | 98 |
| 5 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 85 | 85 |
| 6 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{HSO}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 92 | 96 |
| 7 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{PF}_{6}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{2}$ | 64 | 66 |
| 8 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | --- | $\mathbf{2}$ | --- | --- |
| 9 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{UHP}_{2}$ | $\mathbf{2}$ | 44 | 45 |
| 10 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{TBHP}^{2}$ | $\mathbf{2}$ | $<1$ | $<1$ |
| 11 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | --- | 13 | 13 |
| 12 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | 92 | 93 |
| 13 | $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathrm{KReO}_{4}$ | 93 | 94 |
| 14 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{5}$ | 90 | 91 |
| 15 | $\left[\mathrm{C}_{12} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathbf{7}$ | 92 | 93 |

[^0]It is important to note that both the sulfides and hydrogen peroxide are completely soluble in $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] / \mathbf{2}$, therefore being a more efficient and completely homogeneous oxidation system. Reactants and products are both easily removed from the reaction mixture via extraction with diethyl ether, which is immiscible with ILs used in this work.

### 3.2.3 Influence of the reaction temperature

The oxidation of thioanisole under different temperatures was investigated as well. As shown in Figure 2, a higher reaction temperature leads to an acceleration of the thioanisole oxidation. A lower temperature, however, is disadvantageous for the oxidation reaction and the yield is less than $10 \%$ at $0^{\circ} \mathrm{C}$. Therefore, a reaction temperature of $60^{\circ} \mathrm{C}$ was chosen for the further improvement of the reaction conditions.

Figure 2. Catalytic oxidation of thioanisole in the $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] / 2$ system at different temperatures. Reaction condition: 10 mmol substrate, $5 \mathrm{~mol} \% 2,40 \mathrm{mmol} \mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ in $2 \mathrm{~mL}\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] ; \mathrm{t}=1.5 \mathrm{~h}$.

### 3.2.4 Influence of the substrate/catalyst ratio

The influence of the substrate to catalyst ratio was also studied (Figure 3). The reaction led to a yield of $75 \%$ within 90 min when a substrate to catalyst ratio of 100:1 was applied. Lowering the ratio of substrate to catalyst led to higher yields. In this case, in order to obtain the actual catalytic activity of compound $\mathbf{2}$ and complete oxidation reaction in a short period of time, 20:1 appears to be the optimal ratio.

Figure 3. Reaction kinetics of thioanisole in $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] / \mathbf{2}$ at $60^{\circ} \mathrm{C}$ using different substrate-to-catalyst (S/C) ratios; $\mathrm{t}=1.5 \mathrm{~h} . \mathrm{S} / \mathrm{C}: 100 / 1(\mathbf{\Delta}), 100 / 3(\bullet), 100 / 5(\square)$.

### 3.2.5 Selective oxidation of different sulfides

The optimized reaction was carried out using 2 as catalyst for oxidation of sulfides to sulfones in the conventional ionic liquid $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right]$ at $60^{\circ} \mathrm{C}$ (Scheme 1).

Scheme 1. Oxidation of sulfides to sulfones with $\mathrm{H}_{2} \mathrm{O}_{2}$ using [ $\left.\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]$ (2) as catalyst.
To generalize the developed protocol, a wide range of sulfides with different functional groups was oxidized under the same conditions. The results are listed in Table 3 and show that sulfones can be obtained in high yields using $35 \%$ hydrogen peroxide at $60{ }^{\circ} \mathrm{C}$. Good catalytic activity and selectivity were obtained for all tested sulfides. Interestingly, dialkyl sulfides (Entries 8 and 14) were more easily oxidized (within 1 h ) than diaryl sulfides (Entries 9-11, 15), indicating that the steric hindrance was an important factor in this reaction. For the oxidation of various phenyl-ring substituted sulfides to corresponding sulfones, the electronic nature and the position of the substituents had less effect on the yield and selectivity of the product sulfones (Entries 2-4). Furthermore, another useful feature of the presented protocol is that functional groups, such as double bonds, hydroxyl groups and esters are also tolerated and no epoxidation and aldehyde formation is observed (Entries 7, 12 and 13).
The oxidation of dibenzothiophene is of current interest because of its presence in diesel fuels. It is regarded as a possible cause of acid rain and aerosols. ${ }^{[45-47]}$ In the conventional process, hydrodesulfurization is used to remove sulfur e.g. from dibenzothiophene, a process that is far from the requirements of environmental legislations. ${ }^{[48-49]}$ Oxidation of thiophenes in fuels
followed by extraction of the sulfone products is one of the few better methods available for sulfur removal. ${ }^{[50-52]}$ In the present protocol, involving a recyclable medium and catalyst allows a relatively easy catalytic oxidation of dibenzohiophene to sulfone in a one-pot reaction with quantitative yields under mild conditions (Entry 15). This methodology could be adapted to the removal of sulfur-containing compounds from petroleum-derived fuels.

Table 3. Oxidation of sulfides to sulfones with $\mathrm{H}_{2} \mathrm{O}_{2}$ using 2 as catalyst in $\left[\mathrm{C}_{4} \mathrm{mim}\right] \mathrm{BF}_{4}$ at $60{ }^{\circ} \mathrm{C}^{[\text {a] }}{ }^{\text {a }}$

### 3.2.6 Recycling of the catalyst

It is noteworthy that the system described in this work can be reused for at least ten cycles (Table 4). Ten consecutive preparations of methyl phenyl sulfone showed no significant loss in yield compared with the fresh catalyst, proving that this system had consistent activity during the recycling experiments. In addition, the catalyst is very well soluble in conventional ionic liquids, which is a very important feature for practical and efficient applications of catalytic processes.

Table 4. The recycling of $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right] / \mathbf{2}$ in the oxidation of thioanisole. ${ }^{[a]}$

| Cycle | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

| Yield $^{[\mathrm{cc}]}[\%]$ | 96 | 95 | 96 | 93 | 94 | 91 | 90 | 92 | 93 | 92 |

${ }^{[a]}$ Reaction conditions: 10 mmol thioanisole, $5 \mathrm{~mol} \%$ of catalyst 2, 40 mmol of $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ at $60{ }^{\circ} \mathrm{C}$;
${ }^{[b]}$ Determined by GC on the crude reaction mixture using internal standard technology;
${ }^{[c]}$ Isolated yields after column chromatography.

This approach is a significant improvement in comparison to the procedure reported by McKervey et al. using homogneous $\operatorname{Re}(\mathrm{V})$ catalysts and UHP for oxidation of sulfides in acetonitrile, where the reaction times are considerably higher and the catalyst can not be reused. ${ }^{[53]}$ The IPILs are more efficient catalysts and recycling provides environmental benefits and economic viability.

### 3.3 Conclusion

A simple, efficient and green method for oxidation of sulfides to sulfones was developed using novel perrhenate-containing ionic liquids as catalysts and hydrogen peroxide as oxidant. Perrhenate has so far merely been regarded as deactivated decomposition product of MTO or related catalytically active compounds during oxidation reactions. This is very first report on the catalytic activity of perrhenate for the oxidation of sulfides with peroxides in homogeneous phase. The IPILs exhibit good catalytic abilities; a series of sulfones were obtained with high yields under mild reaction conditions. It was demonstrated that IPILs could be reused at least ten times without considerable loss of activity. The conversion and yield did not decrease on recycling and the products obtained were the desired sulfones, providing an environmentally benign chemical process with potential for industrial applications.

### 3.4 Experimental section

### 3.4.1 General

All preparations and manipulation involving air sensitive materials were performed using standard Schlenk techniques under argon atmosphere. Solvents were dried by standard procedures ( $\mathrm{Et}_{2} \mathrm{O}$ over $\mathrm{Na} /$ benzophenone; $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ over $\mathrm{CaH}_{2}$ ), distilled under argon and kept over $4 \AA$ molecular sieves. All chemicals (purchased from Acros Organics or Aldrich) were of analytical grade and used as received. ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were recorded on a Bruker Avance DPX-400 spectrometer and chemical shifts are reported relative to the residual signal deuterated solvent. IR spectra were recorded on Varian FTIR - 670 spectrometer, using a

GladiATR accessory with a diamond ATR element. Thermogravimetry coupled with mass spectroscopy (TG-MS) was conducted utilizing a Netzsch TG209 system; typically about 10 mg of each sample were heated form $25^{\circ} \mathrm{C}$ to $1000{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Differential Scanning Calorimetry (DSC) was performed on a Q2000 series DSC instrument; typically about 2 mg of each sample were heated from $-100{ }^{\circ} \mathrm{C}$ to $150{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Density was measured by an Anton Paar DMA4500 densimeter. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II. Melting points were determined by MPM-H2 melting point meters. TLC was performed on silica gel 60F254 plates procured form E. Merck. Silica gel ( $0.06-0.2 \mathrm{~mm} 60 \mathrm{~A}$ ) was used for column chromatography. $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right],\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{NTf}_{2}\right],\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{HSO}_{4}\right]$ and $\left[\mathrm{C}_{4} \mathrm{mim}\right] \mathrm{PF}_{6}$ were synthesized according to literature procedures. ${ }^{[41-43]}$

### 3.4.2 Synthetic method and characterization data

The imidazolium perrhenates $\mathbf{1 - 7}$ are prepared according to a published procedure. ${ }^{[40]}$ The exchange of 1-alkyl-3-methylimidazolium bromide $\left[\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}+1} \mathrm{mim}\right] \mathrm{Br}(\mathrm{n}=2,4,5,6,8,10,12$; $\mathrm{mim}=3$-methylimidazolium) is achieved by hydroxide via ion exchange resin and subsequent addition of $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and stirring at $70^{\circ} \mathrm{C}$ for 24 h . The only byproducts are ammonia and water, which can easily be removed in vacuo at elevated temperatures. The ionic liquids 1-7 are characterized by FT-IR, ${ }^{1} \mathrm{H}-,{ }^{13} \mathrm{C}$-NMR spectroscopy and elemental analysis.

### 3.4.3 General procedure for the oxidation of sulfides

To a stirred solution of sulfide ( 10 mmol ) and $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right](0.1952 \mathrm{~g}, 5 \% \mathrm{~mol})$ in $\left[\mathrm{C}_{4} \mathrm{mim}\right]\left[\mathrm{BF}_{4}\right](2 \mathrm{~mL})$, an aqueous solution of hydrogen peroxide ( $35 \%$ in water) ( $3.5 \mathrm{~mL}, 40$ $\mathrm{mmol})$ is added in 2 to 3 portions at $60^{\circ} \mathrm{C}$. The progress of the reaction is followed by TLC. The reaction mixture is extracted with diethyl ether $(5 \times 10 \mathrm{~mL})$ and the extract is dried over anhydrous $\mathrm{MgSO}_{4}$. The yield and selectivity of methyl phenyl sulfone are calculated from calibration curves ( $r^{2}>0.999$ ) recorded using 3-methylanisole and 1,4-diacetylbenzene as inhternal standard. The crude product is obtained by rolling evaporation and purified by column chromatography separation (silica gel using hexane/ethyl acetate $90: 10 \mathrm{v} / \mathrm{v}$ ). The RTIL phase is diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and then treated with $\mathrm{MnO}_{2}$ to destroy the excess peroxide. The obtained liquid is firstly dried over anhydrous $\mathrm{MgSO}_{4}$ and then in vacuo for 4 h at $50{ }^{\circ} \mathrm{C}$ to remove $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Fresh substrate and hydrogen peroxide are then added for a new reaction cycle. All products are characterized by melting point, ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{NMR}$ and IR spectroscopy.

# 4 Oxidation of sulfides to sulfoxides mediated by ionic liquids 

This chapter originated from the following publication:<br>Bo Zhang, Ming-Dong Zhou, Mirza Cokoja, János Mink, Shu-Liang Zang and Fritz E. Kühn*

RSC advances 2012, 2, 8416-8420.

### 4.1 Introduction

The oxidation of sulfides is of considerable significance for industrial chemistry. The removal of sulfur-containing compounds is an important process in fuel industry. ${ }^{[1]}$ Therefore, research efforts focus on cost-efficient liquid phase processes, such as the oxidation of sulfides, which are corrosive agents for car engines and problematic for the environment. Furthermore, the selective transformation of organic sulfides to sulfoxides is of high interest in the synthesis of fine chemicals. Sulfoxides are valuable intermediates for the construction of various fine chemicals as useful building blocks in asymmetric synthesis. ${ }^{[2]}$ Thus, there is high demand for a low cost, efficient and highly selective method for the oxidation of sulfides to sulfoxides. There are numerous reports on the oxidation of sulfides to sulfoxides using molecular $\mathrm{V}-,{ }^{[3]}$ $\mathrm{Re}-,{ }^{[4]} \mathrm{Fe}-,{ }^{[5]} \mathrm{Mn}-,{ }^{[6]} \mathrm{Ti}-{ }^{[7]} \mathrm{Mo}^{[8]}$ and $\mathrm{W}_{-}{ }^{[9]}$ based catalysts in organic solvents. However, these catalysts bear several disadvantages: firstly, the syntheses of the catalysts are often quite demanding, which renders them expensive. Secondly, over-oxidation to sulfones can often not be prevented. Some catalyst-free oxidations of sulfides were reported before. ${ }^{[10]}$ However, these reactions are usually quite time-consuming and accompanied by destruction of functional groups.

Room temperature ionic liquids (RTILs) have received much attention due to their unique properties, such as negligible volatility, broad liquid temperature ranges and the ability to dissolve a wide range of inorganic and organic compounds. ${ }^{[1]]}$ In the last 10 years, RTILs were applied as alternative reaction media for a plethora of catalyzed reactions, ${ }^{[12]}$ including the oxidation of sulfides to sulfones. ${ }^{[13]}$ Previously, we and others have shown that ILs are very convenient reaction media for the epoxidation of olefins catalyzed by organometallic Re- ${ }^{[14]}$ and Mo-compounds. ${ }^{[15]}$ The catalytic activities in ILs surpass those achieved in organic solvents. ${ }^{[16]}$ More recently, we discovered that ILs may have a beneficial effect on the activation of $\mathrm{H}_{2} \mathrm{O}_{2}$ in olefin epoxidation. ${ }^{[17]}$ In this work, a novel, efficient, highly selective
and catalyst-free approach for the oxidation of sulfides to sulfoxides in ILs is reported.

### 4.2 Results and discussion

### 4.2.1 Influence of different solvents and oxidants

Thioanisole was treated in a preliminary study with various oxidants in different reaction media to elucidate optimal reaction conditions (Scheme 1). It is known that the oxidant selection is very important for the oxidation of sulfide to sulfoxide and a variety of oxidants such as $\mathrm{KMnO}_{4},{ }^{[18]} \mathrm{NaClO}_{4},{ }^{[19]}$ molecular halogens, ${ }^{[20]} \mathrm{NBS}^{[21]}$ and tert-butyl hydroperoxide (TBHP). ${ }^{[22]}$ However, these oxidants are disadvantageous due to their low oxygen content, which not only makes product isolation difficult, but also leads to the formation of harmful byproducts. $\mathrm{H}_{2} \mathrm{O}_{2}$ is a good alternative oxidant for such a process not only due to its low cost and high oxygen content but also for being an environmental benign reagent, forming only water as byproduct. In this study, the activity of $\mathrm{H}_{2} \mathrm{O}_{2}$ for the oxidation of various sulfides using several ILs such as $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ ( $\mathrm{Bmim}=1$-butyl-3-methylimidazolium), [Emi][SE] (1-ethyl-3-ethylimidazolium ethyl sulfate), $[\mathrm{Bmim}]\left[\mathrm{HSO}_{4}\right]$ and $[\mathrm{Dbim}]\left[\mathrm{BF}_{4}\right]$ (1,2-dimethyl-3-butylimidazolium) both as solvent and promoter was examined. For sake of comparison, several other reactions using organic solvents, or different oxidants such as UHP and TBHP were also examined. All these results are summarized in Table 1.

Scheme 1. Oxidation of sulfides to sulfoxides.

It is seen in Table 1 that solvent selection is very important for sulfide oxidation. A high yield can be obtained only if the $\mathrm{H}_{2} \mathrm{O}_{2}$ solution can be dissolved in the selected solvent forming a homogeneous reaction system. In the case of using $n$-hexane, toluene or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as solvent (Entries 1-3), a clear biphasic solution was observed, leading to a low sulfoxide yield (< $30 \%$ ). Conversely, a high yield ( $>65 \%$ ) can be obtained when using $\mathrm{CH}_{3} \mathrm{CN}$, methanol and ILs as solvent since all of them form a homogeneous phase with the $\mathrm{H}_{2} \mathrm{O}_{2}$ containing phase (Entries 5, 7, 10-12). Additionally, the polarity of the reaction medium may also be an important factor for the oxidation of sulfides. Methanol, despite very good conversion and yield, allows only quite long reaction time ( 18 h ) and functional group decomposition
occurs. ${ }^{[10 b]}$ The reaction becomes much faster when using ILs as reaction media (4 h) (Entries 7, 10-12). A high conversion ( $98 \%$ ) and good yield ( $95 \%$ ) within 4 h reaction time can be achieved in $[\mathrm{Bmim}] \mathrm{BF}_{4}$ as solvent (Entry 7). This is mainly because that the applied IL acts not only as a solvent but also an activator in the reaction system. A more detailed discussion of the interaction between IL and $\mathrm{H}_{2} \mathrm{O}_{2}$, will be given in the spectroscopic part. Although most ILs in Table 1 represent high conversions (> $89 \%$ ) and yields (> $80 \%$ ), $\left[\mathrm{Bmim}^{2}\right]\left[\mathrm{BF}_{4}\right]$ exhibits better stability than other ILs (such as $[\mathrm{Bmim}]\left[\mathrm{HSO}_{4}\right]$, [Emi][SE]). The oxidation of thioanisole is completed within 4 h and less than $3 \%$ of sulfone is formed, even if the reaction time of 24 h is allowed. Therefore, $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ was selected as solvent. The oxidation behavior in the IL system was also investigated (Entries 6-9). A blank experiment without oxidant was carried out and no significant oxidation was observed within 24 h (Entry 6 ), indicating that the oxygen source for the synthesis of sulfoxide is not air. For different oxidants such as TBHP and UHP, very low conversions ( $6 \%$ for TBHP, $13 \%$ for UHP) and yields (5 \% for TBHP, 12 \% for UHP) were obtained (Entries 8, 9).

### 4.2.2 Selective oxidation of different sulfides

To generalize the developed protocol, a series of sulfides with different functional groups were selected (see Table 2) and all oxidation reactions were performed under the same conditions as Entry 7 in Table 1. Among all investigated substrates, dimethyl sulfide (Entry 6) was more easily oxidized (within 2 h ) than other substrates with bulkier substituents. This indicates that the steric hindrance is an important factor for this reaction. In general, sulfides
bearing strong electron-donating alkyl and alkene groups (Entries 1, 2, 5, 6, 9 and 11) display very good yields (> $80 \%$ ). On the other hand, the oxidation of sulfides containing electron-withdrawing groups such as alcoholate (Entry 7), ester (Entry 8), acetonyl (Entry 10) or less electron-donating groups (Entries 3, 4 and 12-14) lead to lower yields. Presumably, electron-donating groups increase the nucleophilicity of the sulfur atom and hence the reactivity of the substrates. Notably, neither epoxidation of the double bond of allyl phenyl sulfide (Entry 9) nor oxidation of the hydroxy group (Entry 7) was observed. Although the oxidation of diphenyl sulfide (Entries 3) requires a higher temperature compared to other aryl sulfides, the presented method still exhibits a relatively easy way to obtain diphenyl sulfoxides in a one-pot reaction. The reactivity of thioethers is affected by the nucleophilicity of the sulfur atom and the steric hindrance of the substituted groups. Higher reactivity is always obtained in the case of strong electron-donating groups and with smaller substituents.

Table 2. Oxidation of sulfides to sulfoxides with aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ in $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$. ${ }^{\text {a }}$

### 4.2.3 Reaction mechanism

Regarding the mechanism of this reaction, the interaction between the ionic liquid and $\mathrm{H}_{2} \mathrm{O}_{2}$ appears to be crucial. Organic sulfides are oxidized by hydrogen peroxide in an heterolytic process involving the nucleophilic attack of the sulfur atom on the oxygen. ${ }^{[23]}$ This also explains the faster oxidation rate of aliphatic sulfides, which are more nucleophilic than aromatic sulfides. It may be assumed that the $\mathrm{BF}_{4}$ anion of the ionic liquid forms a hydrogen bond with $\mathrm{H}_{2} \mathrm{O}_{2}$ and increases the electrophilic ability of a peroxide oxygen atom of $\mathrm{H}_{2} \mathrm{O}_{2}$,

## Chapter 4

and at the same time assists the leaving group $\mathrm{H}_{2} \mathrm{O}$ in departing from the reaction intermediate (Scheme 2). ${ }^{[10 c]}$ However, it is very important to exclude other possible interactions with hydrogen peroxide. A thinkable scenario would be the reaction of hydrogen peroxide with the $\mathrm{BF}_{4}$ anion, which would generate hydrofluoric acid, or protons, respectively, which are also known to catalyze the oxidation of sulfides. ${ }^{[24]}$ Further, hypothetically, an oxygen atom could interact with the imidazolium cation. The interaction of $\mathrm{H}_{2} \mathrm{O}_{2}$ would be strongest with the hydrogen atom in the $\mathrm{C}_{2}$ position of the imidazolium ring, since the two neighboring N atoms have a relatively strong electron withdrawing ability, rendering the $\mathrm{C}-\mathrm{H}$ bond more acidic.

$\downarrow$

Scheme 2. Suggested mechanism
A number of spectroscopic examinations of the interactions between water and ionic liquids were performed to date. ${ }^{[25]}$ Lendl et al. found that water interacts with $\left[\mathrm{BF}_{4}\right]^{-}$via hydrogen bonding. ${ }^{[26]}$ A similar interaction between the anion of the IL and hydrogen peroxide could be expected. IR, Raman and NMR spectroscopy are convenient tools to support this hypothesis.

## Chapter 4

Figure 1. IR spectra in the range of 900 to $1200 \mathrm{~cm}^{-1}$ for the treatment of [ Bmim$] \mathrm{BF}_{4}$ with different $\mathrm{H}_{2} \mathrm{O}_{2}$ concentrations. The lines represent the spectra for $0.23,0.53,1.5,3.8, \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{H}_{2} \mathrm{O}_{2}$ concentrations from top to bottom (the topmost line represents pure $\left.[\mathrm{Bmim}] \mathrm{BF}_{4}\right)$.

Figure 2. Raman spectra in the range of 750 to $780 \mathrm{~cm}^{-1}$ for the treatment of $[\mathrm{Bmim}] \mathrm{BF}_{4}$ with different $\mathrm{H}_{2} \mathrm{O}_{2}$ concentrations. The lines represent spectra for 3.4 and $4.1 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{H}_{2} \mathrm{O}_{2}$ concentrations from top to bottom (the topmost line represents pure $[\mathrm{Bmim}] \mathrm{BF}_{4}$ ).

Figure 3. Raman spectra of $\mathrm{H}_{2} \mathrm{O}_{2}$ (solid curve), $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]+\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ (dashed curve) in the range of 840 to $950 \mathrm{~cm}^{-1}$.

In order to answer the question, which type of interaction is most likely responsible for the activation of hydrogen peroxide, we performed vibration and nuclear magnetic resonance spectroscopic studies of the ionic liquid $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ before and after treatment with hydrogen peroxide. Figures 1 and 2 show the IR and Raman spectra of the $\mathrm{B}-\mathrm{F}$ region of $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ at different $\mathrm{H}_{2} \mathrm{O}_{2}$ concentrations. Pure $[\mathrm{Bmim}] \mathrm{BF}_{4}$ has been examined in this range as well, bands were assigned as in previous reports. ${ }^{[25 i]}$ In this study, we concentrated on BF stretching vibrations regions of $900-1200 \mathrm{~cm}^{-1}$ for IR and $750-780 \mathrm{~cm}^{-1}$ for Raman as they are representative of structural changes in $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$.
When increasing the $\mathrm{H}_{2} \mathrm{O}_{2}$ molar fraction, the symmetric $\mathrm{BF}_{4}$ stretching band only slightly shifts to a higher wavenumber (Fig. 1). Three bands have been observed at $\sim 1045 \mathrm{~cm}^{-1}, \sim 1033$ $\mathrm{cm}^{-1}, \sim 1016 \mathrm{~cm}^{-1}$ for the pure ionic liquid. ${ }^{[25 \mathrm{i}]}$ The $\mathrm{BF}_{4}$ anion displays $T_{d}$ symmetry resulting in four bands. Two of these bands are polarized two are depolarized in Raman, and one band should be triplet in IR. However the three bands change into two (at $\sim 1068 \mathrm{~cm}^{-1}, \sim 1025 \mathrm{~cm}^{-1}$ ) after the addition of $\mathrm{H}_{2} \mathrm{O}_{2}$, due to the interaction between $\mathrm{H}_{2} \mathrm{O}_{2}$ and the $\mathrm{BF}_{4}$ anion. A B-F... H hydrogen bond may be assumed thus leading to a widening of the corresponding band (as compared to B-F). The original three bands have changed into two with the increasing concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$, accordingly. In the Raman spectra, the symmetric stretching mode (B-F) of the ionic liquid is shifted from $\sim 764 \mathrm{~cm}^{-1}$ (pure form) to $767 \mathrm{~cm}^{-1}$ (Figure 2). This finding is matched with the IR spectra, which also gives only a minor shift on the B-F vibrational band after the addition of $\mathrm{H}_{2} \mathrm{O}_{2}$. The $\mathrm{O}-\mathrm{O}$ vibration band of $\mathrm{H}_{2} \mathrm{O}_{2}$ were also studied with Raman techniques (Figure 3). The shift difference of $v(\mathrm{O}-\mathrm{O})$ is about $5 \mathrm{~cm}^{-1}$ between pure $\mathrm{H}_{2} \mathrm{O}_{2}\left(\sim 876 \mathrm{~cm}^{-1}\right)$ and IL $+\mathrm{H}_{2} \mathrm{O}_{2}\left(\sim 871 \mathrm{~cm}^{-1}\right)$, suggesting the $\mathrm{H}_{2} \mathrm{O}_{2}$ is weakly
interacting. Furthermore, ${ }^{11} \mathrm{~B}$ NMR and ${ }^{19} \mathrm{~F}$ NMR were also performed to show hydrogen bonding in this system. The ${ }^{11} \mathrm{~B}$ NMR spectrum showed one resonance at $-1.86 \mathrm{ppm}\left(\left[\mathrm{BF}_{4}\right]^{-}\right)$. According to the isotope effect of the boron atom ( ${ }^{10} \mathrm{~B}, 19.9 \%$ and ${ }^{11} \mathrm{~B}, 80.1 \%$ ), two singlets were observed in the ${ }^{19} \mathrm{~F}$ NMR with an integral ratio of $\sim 1: 4$ at -148.66 and -148.71 ppm . When adding $\mathrm{H}_{2} \mathrm{O}_{2}$ to the IL, the ${ }^{11} \mathrm{~B}$ NMR resonance showed a slight shift to -2.16 ppm . The corresponding ${ }^{19} \mathrm{~F}$ NMR showed signals at -150.42 and -150.47 ppm .
The spectroscopic investigations further show that the symmetry of the tetrafluoroborate anion has not changed and that no new species such as HF and $\mathrm{BF}_{3}$ are observed, which could in principle be formed by a reaction of $\mathrm{BF}_{4}$ with $\mathrm{H}_{2} \mathrm{O}_{2}$. The slight shift of the $\mathrm{BF}_{4}$ signals points to a change in the coordination sphere of the anion, such as a weak H...F interaction, but not to the formation of $\mathrm{BF}_{3}$, which would lead to a significantly different peak position due to the symmetry change. On the other hand, the stretching modes of the imidazolium ring C-H groups (Raman and IR scattering contributions in the range of $3000-3500 \mathrm{~cm}^{-1}$ ) should be affected by this replacement. Yet, the measurements did not show appreciable changes in positions, maybe as a consequence of the difficulty of the spectral deconvolution due to the overlap between the $\mathrm{C}-\mathrm{H}$ and the $\mathrm{O}-\mathrm{H}$ stretching regions, especially for a high water content. To better address this issue, substitution of the $\mathrm{C}_{2}$ proton in the imidazolium ring with a $\mathrm{CH}_{3}$ group has been performed for oxidation of thioanisole under the same conditions, using [ Dbim$]\left[\mathrm{BF}_{4}\right]$ as solvent for oxidation of thioanisole (Table 1, Entry 10), yielding sulfoxides in $86 \%$, which proves that an interaction of $\mathrm{H}_{2} \mathrm{O}_{2}$ with imidazolium protons does not take place. ${ }^{[25 e]}$ However, there is no possibility to exclude a situation in which they would interact with each other because of strong electrostatic forces, when the number of "free" cations and anions reaches a certain content. ${ }^{[25 a]}$ With the applied amount of aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$, the interaction between $\mathrm{H}_{2} \mathrm{O}_{2}$ and the $\mathrm{BF}_{4}$ anion is much stronger and more stable than that between $\mathrm{H}_{2} \mathrm{O}_{2}$ and the cation. ${ }^{[25]]}$ Based on the above described experimental and spectroscopic findings and in combination with published literature, ${ }^{[25 e]}$ a hydrogen bond formation between a peroxide oxygen and a $\mathrm{BF}_{4}$ anion appears to be the crucial step during the oxidation reaction in the $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]+\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ system.

### 4.2.4 Recycle ability of IL system

Besides the activity and selectivity, the recyclability and stability of ILs for sulfide oxidations were also investigated. ${ }^{19}$ F NMR ( $\delta=-148.70$ and -148.76 ppm ) and ${ }^{11}$ B NMR ( $\delta=-1.86 \mathrm{ppm}$ ) spectra of the $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ were recorded after four recycling runs, confirming that the IL is stable and no structural change or decomposition took place. Furthermore, as shown in Fig.6,
no significant change of conversion, selectivity and yield were observed. The diphenyl sulfide has been oxidized using recycled $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ as solvent under the same reaction conditions (Table 2, Entry 4). The obtained yield is $68 \%$ after 24 h , proving that this system has constant activity and stability during the recycling experiments.

Figure 6. Oxidation of thioanisole with $\mathrm{H}_{2} \mathrm{O}_{2}$ in $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ at $25^{\circ} \mathrm{C}$ after four reaction runs.

### 4.3 Conclusion

A selective and efficient method for the oxidation of sulfides to the corresponding sulfoxides has been developed. The sulfoxidation can be performed under mild conditions without any catalyst or additional activation reagent when hydrogen peroxide is present. The good stability of this system is supported by ${ }^{19} \mathrm{~F}$ - and ${ }^{11} \mathrm{~B}$ - NMR spectroscopic results. No significant decrease of activity has been observed after four runs. According to IR, Raman and NMR examinations, the IL used in this system assists the nucleophilic attack of the sulfur atom by hydrogen bond formation between a OH group and a $\left[\mathrm{BF}_{4}\right]^{-}$anion. High selectivity and seemingly good recyclability, as well as the absence of classical (and often quite expensive) molecular catalysts together with mild conditions make this method useful for the oxidation of sulfides to sulfoxides.

### 4.4 Experimental section

### 4.4.1 General

All reactions were performed in oven-dried glassware under an argon atmosphere using standard Schlenk techniques. All solvents were collected from purification systems and kept
over molecular sieves. ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR, ${ }^{19} \mathrm{~F}$ NMR and ${ }^{11} \mathrm{~B}$ NMR spectra were recorded on a Bruker Avance DPX-400 spectromete. IR spectra were recorded on Varian FTIR-670 spectrometer, using a GladiATR accessory with a diamond ATR element. Gas chromatography-mass spectroscopy (GC-MS) analysis was performed on an Agilent 6890 instrument using a capillary column ( $30 \mathrm{~m} \times 0.25 \mathrm{~mm} \times 0.25 \mu \mathrm{~m}$ ) with MS detector. Raman spectra were recorded on a Bio-Rad FTS-60A. Melting Pointing was meausred by metling point meters MPM-H2. TLC was performed on silica gel 60 F 254 plates procured from E. Merck. Silica gel ( $0.06-0.2 \mathrm{~mm} 60 \mathrm{~A}$ ) was used for column chromatography. All chemicals were purchased from Acros and ABCR and used without further purification. $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$, $[\mathrm{Emi}][\mathrm{SE}]$ and $[\mathrm{Bmim}]\left[\mathrm{HSO}_{4}\right]$ were synthesized according to literature procedures. ${ }^{[27-29]}$

### 4.4.2 Typical procedure for the oxidation of the sulfides in $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$

To the stirred solution of thioanisole ( $1.18 \mathrm{~mL}, 10 \mathrm{mmol}$ ) in $4 \mathrm{~mL}[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$, an aqueous solution of $\mathrm{H}_{2} \mathrm{O}_{2}(1.75 \mathrm{~mL}, 20 \mathrm{mmol}, 35 \%)$ was added at room temperature forming a homogeneous reaction solution. The progress of the reaction was followed by TLC. The reaction mixture was extracted with diethyl ether ( $5 \times 10 \mathrm{~mL}$ ) and the extractant was dried over anhydrous $\mathrm{MgSO}_{4}$. The crude product was obtained by rolling evaporation and purified by column chromatography separation (silica gel using hexane/ethyl acetate $90: 10 \mathrm{v} / \mathrm{v}$ ). The RTIL phase was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and treated with $\mathrm{MnO}_{2}$ to destroy the excess peroxide and dried over anhydrous $\mathrm{MgSO}_{4}$, filtrated, and then dried in vacuo for 4 h at $50^{\circ} \mathrm{C}$ to remove $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Fresh substrate and hydrogen peroxide were then added for a new reaction cycle. All products were characterized by ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and IR spectroscopy .

2-(Phenylsulfinyl)ethanol: pale yellow oil; B.p.: $362^{\circ} \mathrm{C}$, found $360-363{ }^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right): 3343 \mathrm{~s}$ $(\mathrm{OH}), 1018 \mathrm{vs}(\mathrm{SO}) ;{ }^{1} \mathrm{H}$ NMR ([D $\left.\mathrm{D}_{6}\right]$-DMSO, 100 Hz , r.t. ppm): $\delta=2.97\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{OH}\right), 3.67$ $\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{SO}\right), 3.84\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{SO}\right), 5.10(1 \mathrm{H}, \mathrm{t}, \mathrm{OH}), 7.54(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.62(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph})$; ${ }^{13} \mathrm{C}$ NMR ([D $\left.{ }_{6}\right]$-DMSO, 100 Hz , r.t. ppm): $\delta=54.32,59.92,123.78,129.20,130.65,144.66$. Methyl 2-(pheylsulfinyl) acetate: pale yellow oil; B.p.: $341{ }^{\circ} \mathrm{C}$, found $342-344{ }^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right)$ : 1043vs (SO); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=3.54(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 3.69\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right)$, $7.39(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.54-7.56(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}$, r.t. ppm): $\delta=52.63,61.34$, 124.03, 129.37, 131.73, 142.92, 165.17.

Phenyl allyl sulfoxide: yellow oil; B.p.: $297{ }^{\circ} \mathrm{C}$, found $297-300^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right): 1037 \mathrm{vs}(\mathrm{SO}) ;{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}$, r.t. ppm): $\delta=3.45\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 5.11\left(1 \mathrm{H}, \mathrm{d}, \mathrm{CH}=\mathrm{CH}_{2}\right), 5.24(1 \mathrm{H}, \mathrm{d}$, $\left.\mathrm{SOCH}_{2}\right), 5.56\left(1 \mathrm{H}, \mathrm{m}, \mathrm{SOCH}_{2}\right), 7.43(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.52(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=59.76,122.85,123.27,124.19,128.01,130.06,141.85$.

Methoxymethyl phenyl sulfoxide: yellow oil; B.p.: $296{ }^{\circ} \mathrm{C}$, found $295-298{ }^{\circ} \mathrm{C}$; $\mathrm{IR}\left(\mathrm{cm}^{-1}\right)$ : $1015 \mathrm{vs} ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=3.68(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 4.53\left(2 \mathrm{H}, \mathrm{s}, \mathrm{SOCH}_{2}\right)$, $7.60(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.66(1 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.95(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=$ $61.19,87.78,128.74,129.23,134.07,137.39$
Phenyl isopropyl sulfoxide: yellow oil; B.p.: $290^{\circ} \mathrm{C}$, found $292-294{ }^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right): 1020 \mathrm{vs}$ (SO); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=1.05(3 \mathrm{H}, \mathrm{d}, \mathrm{Me}), 1.14(3 \mathrm{H}, \mathrm{d}, \mathrm{Me}), 2.75(1 \mathrm{H}, \mathrm{m}$, SOCH), 7.41-7.44 (3H,m, Ph), $7.51(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=$ 13.82, 15.84, 54.45, 124.91, 128.83, 130.93, 141.68.

Benzyl phenyl sulfoxide: white solid; M.p.:124-126 ${ }^{\circ} \mathrm{C}$, found $123-125^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right): 1027 \mathrm{vs}$ (SO); ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=4.10\left(2 \mathrm{H}, \mathrm{m}, \mathrm{SOCH}_{2}\right), 7.02(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.35$ $(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.46(5 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=63.57,124.47,128.26$, 128.46, 128.86, 129.13, 130.37, 131.19, 142.72.

Dibenzyl sulfoxide: white crystalline powder. M.p.: $135{ }^{\circ} \mathrm{C}$, found $135-137{ }^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right)$ : 1028vs (SO); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=3.94\left(4 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{SOCH}_{2}\right), 7.31-7.38$ $(4 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 7.43(6 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C} \operatorname{NMR}\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm$): \delta=57.18,128.42,128.99$, 130.16, 130.86.

Dibenzothiophene oxide: off-white to pale yellow solid. M.p.:194-196 ${ }^{\circ} \mathrm{C}$, found $195-197{ }^{\circ} \mathrm{C}$; IR $\left(\mathrm{cm}^{-1}\right)$ : 1018vs (SO); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=7.56(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ph}), 7.65(2 \mathrm{H}, \mathrm{m}$,
$\mathrm{Ph}), 7.87(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 8.03-8.05(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{~Hz}\right.$, r.t. ppm): $\delta=120.89$, $126.55,128.55,131.55,136.10,144.12$.

# 5 Synthesis and characterization of imidazolium salts with the weakly coordinating $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anion 

This chapter originated from the following publication:<br>Bo Zhang, Mathias Köberl, Alexander Pöthig, Mirza Cokoja, Wolfgang A. Herrmann* and Fritz E. Kühn*

Z. Naturforsch., B: J. Chem. Sci. 2012, 67b, 1030-1036.

### 5.1 Introduction

Weakly coordinating anions (WCAs) have been a subject of intensive research in the past decade due to their increasing importance in coordination chemistry and catalysis. ${ }^{[1-6]}$ These applications have grown out of basic research into the special properties of anions containing hydrocarbon and fluorocarbon functionality such as $\left[\mathrm{SO}_{3} \mathrm{CF}_{3}\right]^{-},\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$and $\left[\mathrm{OTeF}_{5}\right]^{-} .{ }^{[7]}$ Owing to the importance of WCAs both in fundamental and applied chemistry, a new class of WCAs has recently been developed. Robert et al. reported the anions $\left[\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3} \mathrm{M}-\mathrm{LN}-\mathrm{M}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}\right]^{-}$, with $\mathrm{M}=\mathrm{B}$ or Al and the linking group LN being azide, dicyanamide, and imidazolide, which were found to be the most stable and effective activators for olefin polymerization reaction. ${ }^{[8-9]}\left[\mathrm{CB}_{11} \mathrm{H}_{12}\right]^{-}$and related carborane anions developed by Reed et al. were applied in many systems, despite the expensive and time consuming multistep procedures of their preparation. ${ }^{[10]}$
The $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anion, commonly abbreviated as $\mathrm{BAr}{ }^{\mathrm{F}}$, is much more stable as compared to the other anions and frequently used as a counteranion for electrophilic cations. ${ }^{[7,11]}$ It can be introduced by salt metathesis reaction of reagents such as $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$, which was first reported in $1963,{ }^{[12]} \quad\left[\mathrm{Mn}\left(\mathrm{NCCH}_{3}\right)_{6}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]_{2},{ }^{[13]} \quad\left[\mathrm{H}\left(\mathrm{OEt}_{2}\right)_{2}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[14]}$ $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[15]} \quad\left[\mathrm{HN}^{\mathrm{n}} \mathrm{Bu}_{3}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[16]} \quad\left[{ }^{\mathrm{n}} \mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[17]}$ the superacid $\left[\mathrm{C}_{6} \mathrm{Me}_{3} \mathrm{H}_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[18]} \quad\left[\mathrm{Cp}_{2} \mathrm{Zr}\left(\mathrm{CH}_{3}\right)\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],{ }^{[19-20]} \quad\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{[21]} \quad$ and $\left[\mathrm{M}\left(\mathrm{NCCH}_{3}\right)_{6}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]_{2}(\mathrm{M}=\mathrm{Cr}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Zn}, \mathrm{Cu})^{[22-23]}$ with labile or sometimes even covalently bound halides. Recently, imidazolium-based ionic liquids (ILs) have received considerable attention in different research fields. ${ }^{[24-30]}$ The synthesis of ILs bearing $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anions and organic cations such as imidazolium could represent an approach to
combine the advantages of unreactive and stabilizing WCAs and eco-friendly ILs with low vapor pressure. Since $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$-based organic salts with imidazolium cations are quite rare, ${ }^{[31-32]}$ we focused on the synthesis of new ionic compounds consisting of imidazolium cations and $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anions via metathesis reactions. In this report, we present the precursors $\left[\mathrm{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ (1) and $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ (2) as metathesis reagents for the conversion of imidazolium bromides $[\mathrm{Bmim}] \mathrm{Br}$ and $[\mathrm{Dbim}] \mathrm{Br}(\mathrm{Bmim}=$ 1-butyl-3-methylimidazolium; $\operatorname{Dbim}=1,2$-dimethyl-3-butylimidazolium) to yield the imidazolium-based salts $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right](\mathbf{3})$ and $[\operatorname{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right](4)$ with the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$ anion.

### 5.2 Results and discussion

### 5.2.1 Synthesis of $\left[\operatorname{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$

The alkali metal salt $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ was prepared according to literature procedures, ${ }^{[23]}$ but using $\mathrm{C}_{6} \mathrm{~F}_{5} \mathrm{I}$ instead of $\mathrm{C}_{6} \mathrm{~F}_{5} \mathrm{Br}$. The reaction of 1 equiv. $\mathrm{LiC}_{6} \mathrm{~F}_{5}$ with 0.25 equiv. $\mathrm{BCl}_{3}$ in a mixture of diethyl ether and $n$-hexane at low temperatures leads to the formation of $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ under precipitation of LiCl . Subsequent crystallization of $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ from a concentrated solution in acetonitrile yields $\left[\mathrm{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right](\mathbf{1})$ as colorless crystals in a moderate yield of $41 \%$ (Scheme 1).

$$
\left.\left.4 \mathrm{C}_{6} \mathrm{~F}_{5} \mathrm{I} \xrightarrow[-4 n-\mathrm{BuI}]{\substack{n-\mathrm{BuLi}, \mathrm{Et}_{2} \mathrm{O},-78{ }^{\circ} \mathrm{C}}} 4 \mathrm{LiC}_{6} \mathrm{~F}_{5} \xrightarrow[-3 \mathrm{LiCl}]{\substack{\mathrm{BCl}_{3}, \mathrm{Et}_{2} \mathrm{O} \\
-78{ }^{\circ} \mathrm{C}}} \xrightarrow{\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]} \begin{array}{r}
\left.-25^{\circ} \mathrm{C} \mid{ }_{\downarrow}\right] \mathrm{CH}_{3} \mathrm{CN}
\end{array}\right]\left[\mathrm{Li(NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right] .
$$

Scheme 1. Synthesis of the precursor $\left[\mathrm{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ (1).
Compound 1 exhibits very good solubility in polar organic solvents such as acetonitrile and diethyl ether. It is stable at room temperature and can be handled in air for a short period of time ( 5 min ). The ${ }^{1} \mathrm{H}$ NMR spectrum shows one broad singlet at 1.96 ppm originating from free acetonitrile, as a consequence of a fast scrambling with $\mathrm{CD}_{3} \mathrm{CN}$ solvent molecules. The ${ }^{19} \mathrm{~F}$ NMR spectrum exhibits one broad singlet at -133.8 ppm (arising from $8 o-\mathrm{F}$ atoms), one
triplet at -164.0 ppm (attributed to $4 p-\mathrm{F}$ atoms) and one multiplet which can be assigned to 8 $m$-F atoms. According to elemental analysis, the number of coordinated acetonitrile molecules to the lithium cation is four (see Experimental Section). Compound 1 has further been characterized by means of IR spectroscopy. The $v_{\mathrm{CN}}$ absorption band in the IR spectra is shifted from $2254 \mathrm{~cm}^{-1}$ for free acetonitrile to $2279 \mathrm{~cm}^{-1}$ for compound $\mathbf{1}$. The higher energy vibration in the $v_{\mathrm{CN}}$ region ( 2293 and $2306 \mathrm{~cm}^{-1}$ for free acetonitrile and $\mathbf{1}$, respectively) can be assigned to combination of the symmetrical $\mathrm{CH}_{3}$ deformation and the $\mathrm{C}-\mathrm{C}$ stretch that borrows its intensity from the $v_{\mathrm{CN}}$ band. These results are in good agreement with what has previously been reported for related $\mathrm{Cu}(\mathrm{I})^{[33]}$ and $\mathrm{Ag}(\mathrm{I})^{[21]}$ complexes.

### 5.2.2 Crystal structure of $\left[\operatorname{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$

The molecular structure of compound $\mathbf{1}$ is presented in Figure 1. The compound crystallizes in the monoclinic space group $P 2_{1} / n$ with one ion pair in the asymmetric unit. Both central atoms (lithium and boron) exhibit a tetrahedral coordination environment. Selected bond lengths are given in Table 1. The Li-N bond lengths (in average $2.03 \AA$ ) are longer than the Li-O bond lengths of $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ described by Martin et al. (in average $1.95 \AA$ ), ${ }^{[15]}$ which are also listed in Table 1. According to the non-coordinating nature of the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$ anion, the $\mathrm{B}-\mathrm{C}$ bond lengths in $\mathbf{1}$ and $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ are similar. Since the steric demand of the "end-on" - coordinated linear acetonitrile molecules is lower than that of the "side-on" - coordinated diethyl ether molecules, the N -Li-N bond angles in $\mathbf{1}$ exhibit a broader range (103 to $122^{\circ}$ ) than the related O-Li-O bond angles in Martin's diethyletherate (104 to $117^{\circ}$ ).

| Table 1. Comparison of selected bond lengths $(\AA)$ and angles $(\mathrm{deg})$ in $\mathbf{1}$ and $\left[\mathrm{Li}\left(\mathrm{OEt}_{2}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{[15]}$ |  |  |
| :---: | :---: | :---: |

Figure 1. ORTEP view of $\mathbf{1}$ with displacement ellipsoids at the $50 \%$ probability level. H atoms are omitted for clarity. Selected bond lengths ( $\AA$ ) and angles (deg): Li1-N1 2.033(3), Li1-N2 2.041(3), Li1-N3 2.010(3), Li1-N4 2.044(3), Li1-N1-C25 160.2(2), Li1-N2-C27 169.1(2), Li1-N3-C29 169.9(2), Li1-N4-C31 175.5(2), N1-Li1-N2 104.6(2), N2-Li1-N3 103.2(2), N3-Li1-N4 105.5(2), N1-Li1-N4 103.0(2), N1-Li1-N3 121.6(2), N2-Li1-N3 103.2(2).

### 5.2.3 Synthesis of the new imidazolium-BAr ${ }^{\mathrm{F}}$ compounds

In order to obtain the imidazolium salts $\mathbf{3}$ and $\mathbf{4}$, two different starting materials, $\left[\mathrm{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$, were used (Scheme 2). The latter was prepared according to the literature. ${ }^{[21]}$

Scheme 2. Synthesis of $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ (3)

The metathesis reaction of $\mathbf{1}$ with $[\mathrm{Bmim}] \mathrm{Br}$ leads to the formation of $\mathbf{3}$ in a yield of $62 \%$ within 2 h at room temperature. In order to increase the yield and reduce the reaction time, we selected $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ as precursor for the synthesis of the imidazolium- $\mathrm{BAr}^{\mathrm{F}}$ compounds. In the metathesis reaction, silver cations were exchanged by imidazolium cations. The metathesis was performed using dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the dark at room temperature. The reaction mixture was stirred for 10 min , and then filtered through siliceous earth on a Schlenk frit. The solvent was removed under high vacuum. The product was washed with dry $n$-hexane and then dried in vacuo. Typical yields of the purified product were around $89 \%$. In the ${ }^{19} \mathrm{~F}$ NMR spectra of compounds $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $[\mathrm{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ the fluorine
signals are shifted about 2 ppm toward low field, compared to those of $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ (Table 2), indicating that the bromide salts $([\mathrm{Bmim}] \mathrm{Br}$ and $[\mathrm{Dbim}] \mathrm{Br})$ have reacted with $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$.

Table 2. ${ }^{19} \mathrm{~F}$ NMR chemical shifts (ppm) of $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$, $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $[\operatorname{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ in $\mathrm{d}_{6}$-DMSO.

| Compound | $\delta\left({ }^{19} \mathrm{~F}\right)(\mathrm{ppm})$ |  |  |
| :---: | :---: | :---: | :---: |
| $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\left[\mathrm{~B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]\right.$ | -168.4 | -164.0 | -133.8 |
| $[\mathrm{Bmim}] \mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}$ | -165.6 | -161.7 | -131.3 |
| $[\mathrm{Dbim}] \mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}$ | -166.0 | -161.5 | -132.4 |

### 5.2.4 Crystal structures of imidazolium-BAr ${ }^{\mathrm{F}}$ compounds

Crystals of $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $[\mathrm{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ suitable for X -ray crystal structure analysis were obtained by slow diffusion of $n$-hexane into a dichloromethane solution of the corresponding compounds $\mathbf{3}$ and $\mathbf{4}$ are very stable in air for a long time (at least one day) and soluble in polar organic solvents such as ether and dichloromethane. The molecular structures of $\mathbf{3}$ and $\mathbf{4}$ are presented in Figures 2 and 3. Both compounds crystallize in the monoclinic space group $P 2{ }_{1} / c$. The asymmetric unit consists of one anion and one $[\mathrm{Bmim}]^{+}$cation (3) or of two ion pairs [Dbim $]^{+}\left[B\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)\right]^{-}(\mathbf{4})$. No significant cation...anion contacts are observed.

Figure 2. ORTEP view of $\mathbf{3}$ showing vibrational ellipsoids at the $50 \%$ probability level. H atoms are omitted for clarity.

Figure 3. ORTEP view of 4 showing vibrational ellipsoids at the $30 \%$ probability level. H atoms are omitted for clarity.

### 5.2.5 Thermal characterization

Samples of compounds $\mathbf{1 , 3}$ and $\mathbf{4}$ were examined by thermogravimetric analysis (TGA) in combination with online fragment detection via coupled mass spectroscopy (MS), applying a temperature program with a heating rate of $10{ }^{\circ} \mathrm{C} \mathrm{min}^{-1}$ between 30 and $1000{ }^{\circ} \mathrm{C}$. For compound 1, a total weight loss of about $87 \%$ of the original mass was detected. Compound 1 shows its first decomposition onset at $135^{\circ} \mathrm{C}$ and is associated with a weight loss of $c a .9 \%$ of the original mass. The second and final decomposition starts at $220^{\circ} \mathrm{C}$ and corresponds to a weight loss of $70 \%$ at $400^{\circ} \mathrm{C}$. The first step originates from the loss of $\mathrm{CH}_{3} \mathrm{CN}$ molecules as indicated by detection of $\mathrm{CH}_{3}{ }^{+}$and $\mathrm{CN}^{-}$fragments. The second maximum in the MS curves of $\mathrm{CH}_{3} \mathrm{CN}, \mathrm{CH}_{3}{ }^{+}$and $\mathrm{CN}^{-}$fragments is at $285{ }^{\circ} \mathrm{C}$. Simultaneously, maxima in the MS curves of $\mathrm{Li}\left(\mathrm{CH}_{3} \mathrm{CN}\right)^{+}$and $\mathrm{C}_{6} \mathrm{~F}_{5}^{+}$fragments, resulting from the stepwise decomposition of the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anion, are observed at $285{ }^{\circ} \mathrm{C}$. The ionic compounds $\mathbf{3}$ and 4 exhibit a thermal stability beyond $240^{\circ} \mathrm{C}\left(245^{\circ} \mathrm{C}\right.$ for $\mathbf{3}, 270^{\circ} \mathrm{C}$ for $\left.\mathbf{4}\right)$. Furthermore, the thermal behavior of the salts was studied by differential scanning calorimetery (DSC), as shown in Figure 4. Both crystalline salts displayed a sharp melting transition on heating, and crystallized on cooling from the melt. The melting points and crystallization points of $\mathbf{3}$ and $\mathbf{4}$ are $145.0,97.0^{\circ} \mathrm{C}$ and $150.8,70.0^{\circ} \mathrm{C}$, respectively.

Figure 4. Characteristic DSC trances for $\mathbf{3}$ and $\mathbf{4}$ showing the characteristic melting and crystallization points.

### 5.3 Conclusion

In summary, the imidazolium- $\mathrm{BAr}^{\mathrm{F}}$ compounds $\mathbf{3}$ and $\mathbf{4}$ were synthesized using two different precursors. Compounds $\mathbf{3}$ and $\mathbf{4}$ are imidazolium salts bearing the BAr ${ }^{\mathrm{F}}$ anion characterized by X-ray single crystal structure analysis. Whereas the yield of $\mathbf{3}$ is about $62 \%$ when using $\mathbf{1}$ as starting material (after 2 h at $25^{\circ} \mathrm{C}$ ), the yield increases to $89 \%$ when $\mathbf{2}$ is employed (after 10 min at $25^{\circ} \mathrm{C}$ ). The crystal structure of $\mathbf{1}$ was also elucidated by single-crystal X-ray diffraction. The two new imidazolium salts $\mathbf{3}$ and $\mathbf{4}$ have decomposition temperatures (at $245^{\circ} \mathrm{C}$ for 3 and at $270^{\circ} \mathrm{C}$ for $\mathbf{4}$ ) indicative of high thermal stability.

### 5.4 Experimental section

### 5.4.1 General

All reactions were performed in an argon atmosphere using standard Schlenk techniques. Solvents were dried by standard procedures ( $n$-hexane and diethyl ether over $\mathrm{Na} /$ benzophenone; $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ over $\mathrm{CaH}_{2}$ ), distilled under argon and used immediately or stored over molecular sieves. ${ }^{1} \mathrm{H},{ }^{11} \mathrm{~B}$ and ${ }^{19} \mathrm{~F}$ NMR spectrawere recorded on a Bruker Avance DPX-400 spectrometer and referenced to deuterated solvent in the case of the ${ }^{1} \mathrm{H} N M R, \mathrm{C}_{6} \mathrm{~F}_{6}$ for the ${ }^{19} \mathrm{~F}$ NMR, $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ for ${ }^{11} \mathrm{~B}$ NMR respectively. IR spectra were recorded on a Varian FTIR-670 spectrometer, using a GladiATR accessory with a diamond ATR element. Elemental analyses were performed with a Flash EA 1112 series elemental analyzer. Thermogravimetric analysis in combination with online fragment detection via coupled mass
spectroscopy (TGA-MS) was conducted utilizing a Netzsch-STA 409 PC system. Typically, about 10 mg of each sample was heated from 30 to $1000^{\circ} \mathrm{C}$ at $10^{\circ} \mathrm{C} \mathrm{min}{ }^{-1}$. Differential scanning calorimetric analysis (DSC) was performed on a DSCQ2000 from TA instrument (Waters) in the temperature range from 0 to $200{ }^{\circ} \mathrm{C}$ at $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$. Fast atom bombardment mass spectrometry (FAB-MS) was carried out with a Finnigan MAT 90 mass spectrometer. The compound $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ was synthesized according to the literature. ${ }^{[21]}$ All chemicals were purchased from Aldrich, Acros Organics and ABCR and used without further purification.

### 5.4.2 Synthetic method and characterization data

Synthesis of $\left[\mathbf{L i}\left(\mathbf{N C C H}_{3}\right)_{4}\right]\left[\mathbf{B}\left(\mathbf{C}_{6} \mathbf{F}_{5}\right)_{4}\right](\mathbf{1})$ : A 2.5 M solution of $n$-BuLi in $n$-hexane ( 6.8 mL , $17 \mathrm{mmol})$ is slowly added to a mixture of $\mathrm{C}_{6} \mathrm{~F}_{5} \mathrm{I}(5.0 \mathrm{~g}, 17 \mathrm{mmol})$ in 15 mL diethyl ether via syringe at $-78^{\circ} \mathrm{C}$. After 1 h of stirring at $-78{ }^{\circ} \mathrm{C}$, a 1 m solution of $\mathrm{BCl}_{3}$ in $n$-hexane ( 4.3 mL , $4.3 \mathrm{mmol})$ is transferred to the pale yellow reaction mixture via a syringe within 5 min . The resulting suspension ( LiCl is precipitating immediately) is allowed to warm to room temperature. After filtration the solution is dried under vacuum to yield a sticky colorless solid that is washed several times with pentane. A concentrated solution in acetonitrile is stored at $-25{ }^{\circ} \mathrm{C}$ to yield colorless crystals of $\mathbf{1}$. The crystalline product is collected and washed with $n$-hexane. Upon drying under vacuum, 1.5 g ( $41 \%$ yield, 1.8 mmol ) of a colorless solid $\mathbf{1}$ is isolated. - ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}, \mathrm{ppm}$ ): $\delta=1.96$ (s, $12 \mathrm{H}, 4$ $\mathrm{CH}_{3} \mathrm{CN}$ ) ; - ${ }^{19} \mathrm{~F}$ NMR ( $377 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, 298 \mathrm{~K}, \mathrm{ppm}$ ): $\delta=-133.8(\mathrm{~s}, 8 \mathrm{~F}, o-\mathrm{F}),-164.0(\mathrm{t}, 4 \mathrm{~F}$, $p-\mathrm{F}$ ) and -168.4 (m, $8 \mathrm{~F}, m-\mathrm{F}) ;-\mathrm{C}_{32} \mathrm{H}_{12} \mathrm{BF}_{20} \mathrm{LiN}_{4}$ (850.2): calcd. C 45.21, H 1.42, N 6.59; found C 44.21, H 1.36, N 6.22; - Selected IR: $v=2279(\mathrm{w}, \mathrm{CN}), 2306(\mathrm{w}) \mathrm{cm}^{-1}$.

Method 1 for the synthesis of 3 and 4: In a Schlenk tube, $\left[\mathrm{Li}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right](72 \mathrm{mg}$, $90 \mu \mathrm{~mol})$ and $[\mathrm{Bmim}] \mathrm{Br}(20 \mathrm{mg}, 90 \mu \mathrm{~mol})$ are dissolved in $10 \mathrm{~mL} \mathrm{CH}_{2} \mathrm{Cl}_{2}$. The mixture is stirred at room temperature for 2 h , and then filtered via a cannula. After removal of the solvent under high vacuum, the product washed with dry $n$-hexane three times and then dried in a high vacuum for 4 h .

Method 2 for the synthesis of $\mathbf{3}$ and 4: To a solution of $\left[\mathrm{Ag}\left(\mathrm{NCCH}_{3}\right)_{4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right](0.738 \mathrm{~g}, 1$ $\mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, a solution of imidazolium bromide ([Bmim]Br: $0.218 \mathrm{~g}, 1 \mathrm{mmol}$; [Dbim] Br : $0.223 \mathrm{~g}, 1 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ is added at room temperature and the mixture stirred for 10 min under exclusion of light, where upon a colorless precipitate forms. The solution is filtered via a cannula and the solvent removed in vacuo. The product is washed with dry $n$-hexane three times and then dried in a high vacuum for 4 h .

### 5.4.3 Single-crystal X-ray structure determination

Intensity data were collected on an X-ray diffractometer equipped with a CCD detector (APEX II, $\kappa$-CCD), a rotating anode (Bruker AXS, FR591) or a fine-focus sealed tube with $\operatorname{Mo} K \alpha$ radiation $(\lambda=0.71073 \AA)$, and a graphite monochromator using the SMART software package. ${ }^{[34]}$ The measurements were performed on single crystals coated with Paratone oil and mounted on glass capillaries. Each crystal was frozen under a stream of nitrogen. A matrix scan using at least 20 centered reflections was used to determine the initial lattice parameters. Reflections were merged and corrected for Lorenz and polarization effects, scan speed, and background using SAINT. ${ }^{[35]}$ Absorption corrections, including odd and even ordered spherical harmonics were performed using SADABS. ${ }^{[36]}$ Space group assignments were based upon systematic absences and successful refinement of the structures. The structures were solved using the Bruker APEX suite of programs ${ }^{[37]}$ and were refined against all data using Shelxle- $97{ }^{[38]}$ in conjunction with Shelxle. ${ }^{[39]}$ Hydrogen atoms were assigned to ideal positions and refined using a riding model with an isotropic displacement parameter 1.2 times that of the attached carbon atom ( 1.5 times for methyl hydrogen atoms). If not mentioned

## Chapter 5

otherwise, non-hydrogen atoms were refined with anisotropic displacement parameters. Full-matrix least-squares refinements were carried out by minimizing $\Sigma w\left(F o^{2}-F c^{2}\right)^{2}$ with the SHELXL-97 weighting scheme. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. ${ }^{[40]}$ Images of the crystal structures were generated by Platon. ${ }^{[41]}$ Details are summarized in Table 3.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-889186 (1), -889187 (3) and -889188 (4). Copies of the data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif.

# 6 Ionic liquids with weakly coordinating anions: synthesis, properties and application 

This chapter contains unpublished results

### 6.1 Introduction

One of the growing awareness of environmental issues in the $21^{\text {st }}$ century has focused attention on the need for greener and more sustainable ionic liquids (ILs) technologies in chemical industry. ${ }^{[1]}$ ILs make a unique designed platform on which, it is possible to explore different functional attributes in the corresponding cationic and anionic components for different purposes, ${ }^{[2]}$ while retaining the core desirable features of the IL state of matter. ${ }^{[3]}$ It is not surprising that ILs have tremendous applications in a variety of chemical processes and play an important role in green and sustainable chemistry. ${ }^{[4]}$

The physical properties of ILs are connected to many physical observables, but the weaker anion-cation interactions and the size of the ions as measured by the molecular volume $V_{\mathrm{m}}$ probably lead to lower melting salts with lower viscosities and higher conductivities. ${ }^{[5]}$ The strength of these anion-cation interactions is correlated to some extent with the coordination ability and Lewis basicity of the anion. ${ }^{[6]}$ In this case, weakly coordinating anions (WCAs) are good candidates for the synthesis of ILs. ${ }^{[7]}$ In general, traditional ILs usually use WCAs such as $\left[\mathrm{BF}_{4}\right]^{-},\left[\mathrm{PF}_{6}\right]^{-},\left[\mathrm{AlCl}_{4}\right]^{-},\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]^{-}$with imidazolium or pyridinium cation. ${ }^{[1-2]}$ Recently, a new class ionic liquids with weakly coordinating anions (ILWCAs) have been developed. For example, ILs with $\left[\mathrm{Al}\left(\mathrm{OR}^{\mathrm{F}}\right)_{4}\right]^{-}\left(\mathrm{R}^{\mathrm{F}}=\mathrm{C}(\mathrm{Ph})\left(\mathrm{CF}_{3}\right)_{2}, \mathrm{C}\left(\mathrm{CF}_{3}\right)_{3}, \mathrm{C}(\mathrm{H})\left(\mathrm{CF}_{3}\right)_{2}, \mathrm{C}\left(\mathrm{CH}_{3}\right)\left(\mathrm{CF}_{3}\right)_{2}\right)$ imidazolium melts for electrochemical applications were discovered and $\left[\mathrm{Al}\left(\mathrm{OC}(\mathrm{Ph})\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]^{-}$was used for hydrovinylation reaction and had been confirmed to be the most effective in enhancing the conversion. ${ }^{[8]}$ Matsumoto prepared and characterized low melting and low viscous ILs with perfluoroalkyltrifluoroborates. ${ }^{[9]}$ A comprehensive examination of ILs based on carborane ${ }^{[10]}$ or azolate ${ }^{[11]}$ anions were also developed. However, in terms of anion stability, it was shown that the $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]\left(\mathrm{Ar}^{\mathrm{F}}=\mathrm{C}_{6} \mathrm{~F}_{5},-\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)$ were much more stable than above anions, ${ }^{[6,12]}$ which promoted their use in many different research fields. ${ }^{[13]}$ It is known that $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}$were shown to stabilize reactive cations since they have been discovered in our group. ${ }^{[14]}$ For instance, the complex $\left[\mathrm{Ag}(\mathrm{MeCN})_{4}\right]\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]$
exhibited catalytic activity in coupling reactions of terminal alkynes with aldehydes and amines. ${ }^{[15]}$ The complexes $\left[\mathrm{M}(\mathrm{MeCN})_{6}\right]\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]_{2}\left(\mathrm{M}=\mathrm{Mn}^{2+}, \mathrm{Cu}^{2+}, \mathrm{Ar}^{\mathrm{F}}=\mathrm{C}_{6} \mathrm{~F}_{5}\right.$, $\left.-\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2} ; \mathrm{M}=\mathrm{Cr}^{2+}, \mathrm{Fe}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Ar}^{\mathrm{F}}=\mathrm{C}_{6} \mathrm{~F}_{5}\right)$ can be used as initiators for the polymerization of 2-methylpropene yielding polyisobutylenes at moderate temperatures. ${ }^{[16]}$ Moreover, $\left[\mathrm{Mn}(\mathrm{MeCN})_{6}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]_{2}$ served for the synthesis of paramagnetic solids. ${ }^{[17]}$ Owing to the importance of WCAs catalysis application and green chemistry, we focused our study on ILs with $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}\left(\mathrm{Ar}^{\mathrm{F}}=\mathrm{C}_{6} \mathrm{~F}_{5},-\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)$ as the anions, probably representing an approach to combine the advantages of stabilizing WCAs and eco-friendly ILs with low vapor pressure.
Surprisingly, the investigation of potential ILs containing $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}$anions has been largely neglected. For catalysis application, there is quite rare in this field so far. To extend the scope of these promising results, ILs with $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}$as the anion are thus of interest due to the high electrochemical stability of this anion as well as the stabilization of highly reactive.
Here we present the synthesis and characterization of a series of ILs which prepared by combining the organic cations (1-butyl-3-methylimidazolium ([Bmim $]^{+}$), 1,2-dimethyl-3-butylimidazolium ([Dbim $]^{+}$), 1-dodecyl-3-methylimidazolium ( $\left[\mathrm{C}_{12} \mathrm{mim}\right]^{+}$), tetra-butyl-phophonium $\quad\left(\left[\mathrm{P}_{4,4,4,4}\right]^{+}\right), \quad$ tributyl-(tetra-decyl)-phosphonium $\quad\left(\left[\mathrm{P}_{4,4,4,14}\right]^{+}\right)$, tetra-butyl-ammonium ( $\left[\mathrm{N}_{4,4,4,4}\right]^{+}$) and 1,1,3,3-tetramethylguanidium ([TMG] $\left.{ }^{+}\right)$) with two different $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]^{-}$anions (Scheme 1), including the solid state structures determined by single crystal X-ray diffraction. Theses salts enhanced thermal stability, which provided and exploited new chemical materials.

The oxidation of sulfides is of considerable significance for industrial chemistry. The removal of sulfur-containing compounds minimizes the negative health and environmental effects from reducing the sulfur content in fuels. ${ }^{[18]}$ In this aspect, the compound $\mathbf{5 b}$ offers practical advantages without seriously jeopardizing their ultimate application for oxidation of sulfides to sulfoxides. Furthermore, this system can be cycled five times without loss of activity. This method was confirmed to be a green, safe, operationally simple and cost-effective system, which can be further development in industry technology.

### 6.2 Results and discussion

### 6.2.1 Synthesis of WCAILs

WCAILs were synthesized according to the modified literature procedures. ${ }^{[19]}$ Two different strategies were used to prepare the WCAILs (Scheme 2).

$$
\begin{aligned}
{[\mathrm{Cat}] \mathrm{X} } & +\mathrm{MR} \xrightarrow[\text { r.t. }]{\mathrm{CH}_{2} \mathrm{Cl}_{2}}[\mathrm{Cat}] \mathrm{R}+\mathrm{MX} \\
\mathrm{X} & =\mathrm{Br}, \mathrm{Cl} \\
\mathrm{M} & =\mathrm{Li}, \mathrm{Ag} \\
\mathrm{R} & =\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}, \mathrm{~B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}
\end{aligned}
$$

Scheme2. Synthesis of WCAILs
In the first step, $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Li}\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ was synthesized by literature procedure. ${ }^{[19-20]}$ WCAILs $\mathbf{1 a - 7 a}$ and $\mathbf{1 b} \mathbf{- 7 b}$ were obtained by the reaction of $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Li}\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ with [Cat] X in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature for 2 h . However, great care must be taken to insure that all materials were free of moisture and air because $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Li}\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ would getting to be viscous liquid in the presence water and air. After filtration, the solvent was removed under vacuum. The remaining product
was washed with dry pentane, and then dried under high vacuum for one day until a constant weight was achieved. Typical yields of the purified product were 55-62 \%. In order to increase the yield and reduce the reaction time, $\mathrm{Ag}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Ag}\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ was selected as precursor for the synthesis of the WCAILs. $\operatorname{Ag}\left[B\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Ag}\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ was prepared according to the literature procedure. ${ }^{[14]}$ The metathesis was performed in the darkness at room temperature with dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as solvent. The reaction mixture was stirred for 10 min before it was filtered. The filtrate was removed under high vacuum to obtain the rough product. The product was washed with dry pentane and then dried under vacuum for one day. Typical yields of the pure product (spectra, elemental analyses) were up to $85-95 \%$. Under these conditions, satisfactory separation of the byproduct (lithium or silver halides) was usually achieved with filtration. From above results, the best routes typically involved silver salts rather than lithium salts in dry dichloromethane. All WCAILs can be handled in air. The salt $\mathbf{5 a}$ is pale yellow liquid and $\mathbf{5 b}$ is pale yellow crystalline liquid at room temperature. All salts have high solubility in polar organic solvents such as $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CH}_{3} \mathrm{CN}$, common alcohols, but low solubility in $n$-hexane.

### 6.2.2 Solid-state structures

Crystals of $\mathbf{4 a}, \mathbf{7 a}, \mathbf{2 b}$ and $\mathbf{5 b}$ suitable for X-ray crystal structure analysis were obtained by slow diffusion of $n$-hexane into a dichloromethane solution of the corresponding compounds at $-10{ }^{\circ} \mathrm{C}$ in a refrigerator (See Experiment Section for crystallographic details). The diffraction measurements were carried out at low temperatures (between 100 to 200 K ) in order to minimize rotation of the $\mathrm{CF}_{3}$ groups and ensure the accuracy of the evaluation of intermolecular interactions involving F and H atoms.

The compound $\mathbf{4 a}$ crystallizes in the orthorhombic space group $\mathrm{Pca} 2_{1}$ with two formula units per cell. The asymmetric unit consists of two $\left[\mathrm{P}_{4,4,4,4}\right]^{+}$ions and two $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$ions. The OrTEP of the molecule is shown in the Figure 1 with atom labeling. Furthermore, the B-C bond lengths (1.656(2)-1.664 (2)) are shorter than the B-C bond lengths (1.657(4)-1.681(4)) of similar structure $\left[\mathrm{N}_{4,4,4,4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ described by M. Bolte due to different cation, ${ }^{[21]}$ which are listed in Table 1.

Figure 1. ORTEP style plot of compound $\mathbf{4 a}$ in the solid state. Thermal ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity.

Table 1. Comparison of selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right)$.

| Entry | Compound | Bond lengths $(\mathrm{B}-\mathrm{C})$ <br> $(\mathrm{min}-\mathrm{max}) /(\AA)$ | Bond angles $(\mathrm{C}-\mathrm{B}-\mathrm{C})$ <br> $($ min-max $) /\left[{ }^{\circ}\right]$ |
| :---: | :---: | :---: | :---: |
| 1 | $[\mathrm{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ | $1.652(2)-1.655(2)^{19}$ | $101.26(11)-114.60(12)^{19}$ |
| 2 | $[\mathrm{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ | $1.653(3)-1.659(3)^{19}$ | $101.23(14)-114.19(15)^{19}$ |
| 3 | $\left[\mathrm{~N}_{4,4,4,4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ | $1.657(4)-1.681(14)^{21}$ | --- |
| 4 | $\left[\mathrm{P}_{4,4,4,4}\left[\mathrm{~B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]\right.$ | $1.656(2)-1.664(2)$ | $101.39(12)-115.59(13)$ |
| 5 | $[\mathrm{TMG}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ | $1.393(19)-1.661(2)$ | $102.29(10)-113.30(10)$ |
| 6 | $[\mathrm{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]$ | $1.635(2)-1.640(2)$ | $101.85(2)-122.66(14)$ |
| 7 | $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]$ | $1.649(2)-1.653(19)$ | $107.53(10)-111.06(10)$ |

The compound 7a was crystallized in triclinic centrosymmetric space group $P \overline{1}$ with $\mathrm{Z}=2$. It is striking that hydrogen atoms could be located in the difference fourier maps and were allowed to refine freely. Furthermore, the structure of the compound 7a exhibits hydrogen-bonding interactions between the F atom from $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ anion and hydrogen atoms from the $\mathrm{NH}_{2}$ group of 1,1,3,3,-tetramethylguanidine (TMG) cation (Figure 2). Thus, the anion and cation are both restabilized by the extensive hydrogen bond. Representative hydrogen bonds are N1-H1...F3 and N1-H2...F13, whose H-bonds lengths are 2.375, 2.541 $\AA$, respectively. The angle of N1-H1...F3 and N1-H...F13 are $158.33,103.27^{\circ}$, respectively (Table 2). The interactions between cation and anion via hydrogen bond maybe attribute to the hydrogen atom ( $-\mathrm{NH}_{2}$ group) which has the partial positive charge because of relatively stronger electronwithdrawing ability of N atom, is easier to attract to F atom which has the partial negative charge. This is also explained that other compound $\mathbf{4 a}$ is difficult to form
hydrogen bond between cation and anion. According to the non-coordinaing nature of the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$anion, the $\mathrm{B}-\mathrm{C}$ bond lengths of 7 a are much shorter than the structure $[\operatorname{Bmim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],[\mathrm{Dbim}]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right],\left[\mathrm{N}_{4,4,4,4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $\left[\mathrm{P}_{4,4,4,4}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ due to the hydrogen bond between the cation and anion, while the bond angles are similar, which are also shown in Table 1.

Figure 2. ORTEP style plot of compound 7a in the solid state. Thermal ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity.

| Table 2. Interatomic distances $(\AA)$ and angle [ ${ }^{\circ}$ ] |
| :--- | Envolving hydrogen bonded atoms in compound 7a.

| type |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{NH}_{2}-\mathrm{C}_{6} \mathrm{~F}_{5}$ | $\mathrm{~N} 1-\mathrm{H} 1 \ldots \mathrm{~F} 3$ | 3.199 | 2.357 | 158.33 |
| 2 | $\mathrm{NH}_{2}-\mathrm{C}_{6} \mathrm{~F}_{5}$ | $\mathrm{~N} 1-\mathrm{H} 2 \ldots \mathrm{~F} 13$ | 2.862 | 2.541 | 103.27 |

The crystal structure of $\mathbf{2 b}$ is crystallized in monoclinic space group $\mathrm{P} 2_{1} / \mathrm{c}$ with $\mathrm{Z}=4$. The OrTEP of the molecule is shown in Figure 3. It was found that four $\mathrm{CF}_{3}$ groups are disordered over two positions and the butyl-group of the cation is disordered over two positions. Furthermore, no significant cation...anion contacts was observed. This is in coincidence previous observations that the bands that related to hydrogen bonds disappeared when the proton atoms on imidazolium-ring were replaced by the $-\mathrm{CH}_{3}$ groups. ${ }^{[6]]}$ Interestingly, the B-C bond lengths (1.635 (2) - 1.640 (2)) are much shorter than the compounds containing $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ anion (Table 1), probably indicating that there is a little effect of substitution on the bond lengths in the phenyl ring such as $\mathrm{CF}_{3}$ group.

Figure 3. ORTEP style plot of compound 2b in the solid state. Thermal ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity.

The compound $\mathbf{5 b}$ was crystallized in triclinic space group $P \overline{1}$ with $\mathrm{Z}=2$. The structure is shown in Figure 4 and the crystallographic data are summarized in the Experimental Section. It was found that three $\mathrm{CF}_{3}$ groups are disordered over two positions. Interestingly, bond angle (C-B-C) $)_{\min }\left(107.53(10)^{\circ}\right)$ is much bigger than any other compounds containing $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ anion (Table 1), probably due to the steric hindrance effects of longer carbon chain of the cation.

Figure 4. ORTEP style plot of compound $\mathbf{5 b}$ in the solid state. Thermal ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity.

### 5.2.3 Characterization of WCAILs

A series of salts $\mathbf{1 a - 7 a}$ and $\mathbf{1 b} \mathbf{- 7 b}$ have been synthesized and characterized by FT-IR, NMR spectroscopy and elemental analysis (see Experiment Section). Melting points ( $T_{\mathrm{m}}$ ) were determined from differential scanning calorimetry (DSC) experiments. The results are summarized in Table 3. There is a significant lowering of the melting points for all salts with the $\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ anion ( $\mathbf{1 b} \mathbf{- 7 b}$ ) compared to the corresponding $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ anion salts ( $\mathbf{1 a - 7 a}$ ), indicating that increasing anion size is connected with a significant decrease in melting point. ${ }^{[22]}$ The reduction in melting point is most pronounced with $\left[\mathrm{P}_{4,4,4,14}\right]^{+}$cation. In this case, the melting points of salts ( $\mathbf{5 a}$ and $\mathbf{5 b}$ ) are reduced from $\sim 120^{\circ} \mathrm{C}$ to less than $50^{\circ} \mathrm{C}$. While high symmetry compounds ( $\mathbf{4 a}, \mathbf{6 a}, \mathbf{7 a}, \mathbf{4 b}, \mathbf{6 b}$ and $\mathbf{7 b}$ ) lead to high melting points. Therefore, symmetry-breaking (in cations) is considered to be a key driver to the formation of lower melting ionic liquid. ${ }^{[23]}$ Similarly, the melting points for the $\mathbf{2 a}$ and $\mathbf{2 b}$ decreased with increasing alkyl chain length from butyl to dodecyl due to the increasing the cation size and decreasing the cation symmetry. Furthermore, the hydrogen bond between cation and anion maybe another factor for determining the properties, such as melting point. ${ }^{\left[5,{ }^{24]} \text { The melting }\right.}$ point of $\mathbf{5 b}$ is lower compared to the similar salts containing the same anion due to the hydrogen bond. It can be clearly seen that the liquid range for these WCAILs is governed principally by the choice of cation, which has the greatest influence on the lower melting point, IL with $\left[\mathrm{P}_{4,4,4,14}\right]^{+}$cation ( $\mathbf{5 a}$ and $\mathbf{5 b}$ ) showing the lowest temperatures of all.

Thermal stability was measured by using thermogravimetric analysis (TGA), with isocratic heating at $10{ }^{\circ} \mathrm{C} \mathrm{min}^{-1}$ under an inert argon atmosphere. All salts prepared were thermally stable to greater than $240{ }^{\circ} \mathrm{C}$ (Table 3). Interestingly, the salts show slight increase in upper stability temperature on increasing the cation alkyl chain from butyl to dodecyl, as well as on changing from phosphonium to imidazolium cations. In general, $\mathbf{a}$ and $\mathbf{b}$ anion with other type of cations decompose below $200{ }^{\circ} \mathrm{C}$, ${ }^{[15 \mathrm{e}]}$ indicating that this kind of ionic liquids have good thermal stability.

### 6.2.4 Application for oxidation of sulfides to sulfoxides

The oxidation of sulfides to sulfoxides was carried out using WCAILs $\mathbf{5 a}$ and $\mathbf{5 b}$ as reaction media and $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant agent at room temperature. The details concerning the catalytic reaction are given in the experiment part. Oxidation of thioanisole with aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant was found to be strongly solvent dependent. When using 5a as solvent, the yield of sulfoxide is $18 \%$ within 4 h , and the selectivity toward sulfoxide is $90 \%$ probably due to the high viscosity. Higher yields were obtained using $\mathbf{5 b}$ as media. Therefore, $\mathbf{5 b}$ was chosen as media for oxidation of sulfides to sulfoxides with $\mathrm{H}_{2} \mathrm{O}_{2}$ at room temperature (Scheme 3). A blank experiment without oxidant was also investigated and no considerable oxidation was observed within 24 h , indicating that the oxygen source for the synthesis of sulfoxide is not air.

Scheme 3. Oxidation of sulfides to sulfoxides

It can be seen in Figure 5 that with increasing the reaction time, the yield of methyl phenyl sulfoxide increased greatly, while the selectivity of methyl phenyl sulfoxide kept steadily during the reaction. The maximum yield could be achieved after 4 h and no further increase in the yields of methyl phenyl sulfoxides was observed with prolonged reaction time.

Figure 5. Time dependent yield (■) and selectivity $(\Delta)$ of methyl phenyl sulfoxide in the oxidation of thioanisole with $\mathrm{H}_{2} \mathrm{O}_{2}$ in $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$.

To generalize the developed methodology, a wide range of sulfides with different substituted groups were selected to oxidize under the same condition. The results are shown in Table 4. All sulfides were effectively oxidized to the corresponding sulfoxides with good to excellent yields using $35 \%$ hydrogen peroxide at room temperature. Interestingly, a dialkyl sulfide (Entries 3) is more active, affording a very high sulfoxide yield (within 3 h ) than diaryl sulfides (Entries 1, 3-7) due to the steric hindrance. For the oxidation of various phenyl-ring substituted sulfides to corresponding sulfoxides, the electronic nature of the substituents has less effect on the yield and selectivity of the product sulfoxides (Entries 4-7). It is important to note that another useful feature of the presented protocol is that neither epoxidation of the double bond of allyl phenyl sulfide (Entry 6) nor oxidation of the hydroxo group (Entry 7) was observed.

| Table 4. Oxidation of sulfides to sulfoxides with aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$ in $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]^{\mathrm{a}}$ |  |  |  |

[^1]The advantage of this oxidation system is their potential recovery for multiple uses. After oxidation of thioanisole was completed in $\mathbf{5 b}$ IL, the IL phase was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ after extraction sulfide and sulfoxide, and then treated with $\mathrm{MnO}_{2}$ to destroy the excess peroxide. The obtained liquid was dried over anhydrous $\mathrm{MgSO}_{4}$, and then dried under high vacuum until a constant weight was achieved. Five recycling tests were carried out and the results are summarized in Figure 6. It can be seen that no significant loss of yield and selectivity was observed after five runs when thioanisol was used at the test substrate. This system provides the advantage of recycle and stable compared to the other systems which using the organic solvent as media for oxidation of sulfides have been previously reported. ${ }^{[25]}$

Figure 6. Oxidation of thioanisole with $\mathrm{H}_{2} \mathrm{O}_{2}$ in $\mathbf{5 b}$ at $25^{\circ} \mathrm{C}$ after five reaction runs.

### 6.2.5 Reaction mechanism

Regarding the mechanism of this reaction, the interaction between the ionic liquid and $\mathrm{H}_{2} \mathrm{O}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ appear to be crucial. It is known that organic sulfides are oxidized by hydrogen
peroxide in an heterolytic procss involving the nucleophilic attack of the sulfur atom on the oxygen. ${ }^{[26]}$ This also explains the dialkyl sulfides are indeed more easily oxidized than the diaryl sulfides. Concerning the efficiency of our oxidizing system, it can be explained by a specific feature of $\mathbf{5 b}$ ionic liquid which not only act as a solvent but also can be viewed as a promoter for the catalysis. Because of the electron withdrawing character of the $\mathrm{CF}_{3}$ group, the hydrogen bond between the $\mathbf{5 b}$ ionic liquid and $\mathrm{H}_{2} \mathrm{O}_{2}$ or $\mathrm{H}_{2} \mathrm{O}$ is formed and preventes from any further oxidation into sulfone. ${ }^{[27]}$ Furthermore, $\mathbf{5 b}$ ionic liquid is more stable in catalysis reaction compared to the commen ILs such as $\left[\mathrm{BF}_{4}\right]^{-}$or $\left[\mathrm{PF}_{6}\right]^{-}$as anion. Because the hydrofluoric acid HF which comes from the decomposition of $\left[\mathrm{BF}_{4}\right]^{-}$or $\left[\mathrm{PF}_{6}\right]^{-}$as anion ILs in oxidation reaction in the presence of water or hydrogen peroxide was producing. ${ }^{[28]}$
In order to further study the interaction between ILs and $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{O}_{2}$ and support above points as well, several techniques such as infrared vibration and nuclear magnetic resonace have been used to monitor interaction between the dontors and anionic species. In order to understand which hydrogen participated in the hydrogen bonds, deuteroxide has been instead of the pure water for IR measurements. Figures 7 and 8 show the IR spectra of the CF stretching region of $\mathbf{5 b}$ ionic liquid in $\mathrm{D}_{2} \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{O}_{2}$. As can be seen from the Figures, the $\mathrm{CF}_{3}$ stretching modes are expected to be very prominent in the infrared spectrum. Due to the non-equivalence CF bands to interpret as antisymmetric and symmetric stretching mode has no sence. The exact $\mathrm{C}_{3 v}$ local symmetry should produce only two bands $v_{\mathrm{a}}$ (higher) and $v_{\mathrm{s}}$ (lower). Instead, three well developed bands at 1355,1275 and $1119 \mathrm{~cm}^{-1}$ have been deserved in 1a spectrum. The first two bands can be interpreted as individual localized CF stretchings which shows different CF band length and the mutiply structure broad band near $1119 \mathrm{~cm}^{-1}$, is a kind of symmetric stretching mode of different CF bands. This explanation is in agrrement with the literatures data of announced $\mathrm{CF}_{3}$ devrivatives. ${ }^{[29]}$ And accordingly, we can name them as $v>v^{\prime}>v^{\prime \prime}$, repectively. As can be seen from Figure 7, the bands $v$ and $v^{\prime}$ are not shifted, while new bands are formed in the region of $\mathrm{CF}_{3}$ symmetric stretching mode. To obtain fine spectral differences between samples, the second derivative showed in Figure 8. When adding the $\mathrm{D}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{O}_{2}$ into the IL, two new bands at 1115 and $1124 \mathrm{~cm}^{-1}$ or 1114 and $1123 \mathrm{~cm}^{-1}$ are formed, respectively. Furthermore, clear developing of a shoulder near 1085 $\mathrm{cm}^{-1}$ can be seen in Figure 7 for spectrum 2a and 3a which are more clarly identified by second derivatives. In Figure 8, the band at $1085 \mathrm{~cm}^{-1}$ in 2 b and 3 b spectra is getting stronger compared to the pure ionic liquid. These changes can be ascribed to a further distortion of the $\mathrm{CF}_{3}$ local symmetry from $\mathrm{C}_{3 v}$ to $\mathrm{C}_{1}$ which lead to formation of new spectra features by weak coordination, such as hydrogen bond between F from ionic liquid and hydrogen from $\mathrm{D}_{2} \mathrm{O}$ or
$\mathrm{H}_{2} \mathrm{O}_{2}$.

Figure 7. Band CF stretching region of pure $\operatorname{IL}\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]$ (1a, 1b), IL with $\mathrm{D}_{2} \mathrm{O}$ (2a, 2b) and IL with $\mathrm{H}_{2} \mathrm{O}_{2}(3 \mathrm{a}, 3 \mathrm{~b})$.

Figure 8. Second deritative of bond CF symmetric stretching region of pure IL $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ (1b), IL with $\mathrm{D}_{2} \mathrm{O}$ (2b) and IL with $\mathrm{H}_{2} \mathrm{O}_{2}(3 \mathrm{~b})$ (The derivative curves were multiplied by -10 ).

It is known that NMR is sufficiently advanced that, approximate chemical shifts can be predicted for compounds of a known structure and, vice versa, the approximate coordination environment of unknown compounds can be predicted on the basis of chemical shift

## Chapter 6

values. ${ }^{[28 d]}$ Therefore, ${ }^{11} \mathrm{~B},{ }^{19} \mathrm{~F}$ and ${ }^{31} \mathrm{P}$ NMR were also performed to show hydrogen-bonding in the absence and in the presence of water or hydrogen peroxide. The ${ }^{11}$ B NMR spectrum shows one resonance at -6.58 ppm with pure ionic liquid. The spectra recorded exhibits a slight shift to -6.84 ppm after addition $\mathrm{H}_{2} \mathrm{O}$ into IL and -6.75 ppm after $\mathrm{H}_{2} \mathrm{O}_{2}(30 \%)$ addition. The corresponding ${ }^{19} \mathrm{~F}$ NMR shows one signal at -59.55 ppm for the pure IL. The spectroscopic investigations shifts to -61.29 ppm or two signals -60.64 and -61.23 ppm when adding the $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{O}_{2}$ into IL. The slight shift of the $\mathrm{CF}_{3}$ signal points to a change in the coordination sphere of the anion, such as a weak H...F interaction, but not to the formation of $\mathrm{BF}_{3}$ or HF , which would lead to a significantly different peak position due to the symmetry change. On the other hand, the behavior of cation when the environment was changed was also studied. As it can be seen, the ${ }^{31}$ P NMR pattern of two different mixtures is quite different. The signal at 34.95 ppm for the pure IL significantly has been shifted to 33.43 ppm for the mixture with $\mathrm{H}_{2} \mathrm{O}$ and to 33.50 ppm for the mixture with $\mathrm{H}_{2} \mathrm{O}_{2}$, indicating the cation of IL is not changed as well. Based on above described experimental and spectroscopic findings, a hydrogen bond formation between $\mathrm{CF}_{3}$ group of IL and hydrogen peroxide or water appears to be the crucial step during the oxidation reaction.

### 6.3 Conclusion

In continuation of our studies of ionic liquids utilizing N , N '-Dialkylimidazolium, tetrabutylammonium, tetralkylphosphonium, 1,1,3,3-tetramethylguanidium cations with new family $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]$ species have been synthesized and structurally characterized. The synthesis is optimized and simple, and the products can be obtained in high yield. All salts have high thermal stability. It has been shown that the $\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]^{-}$anion salts $(\mathbf{2 b}, \mathbf{3 b}, \mathbf{5 b}$ and 6b) melting points are reduced by below $100{ }^{\circ} \mathrm{C}$ compared to the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{\circ}$ salts, which lead to opportunities to form ILs materials. The melting points of the salts using the tetrabutylammonium and 1,1,3,3-tetramethylguanidium as cation are higher than any other salts due to the high symmetry structure. Increasing the size of the salts has been identified as a common and potentially general characteristic of low melting points with large cation, such as $\mathbf{5 a}$ and $\mathbf{5 b}$. The systematic variation of alkyl substituent on the cation led to usefully predictive trends in melting points. It is important to mention that hydrogen-bonding interactions between $[\mathrm{TMG}]^{+}$and $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$has been discovered.

The ionic liquid $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ can be successfully applied for oxidation of sulfides to sulfoxides without any catalyst. Furthermore, this system can be recycled five
times without any loss of activity. This methodology with mentioned advantages is an improved and environmentally benign way for catalytic process.

### 6.4 Experiment section

### 6.4.1 Gernal

All preparations and manipulation involving air-sensitive materials were performed using standard Schlenk techniques under argon atmosphere. Solvents were dried by standard procedures ( $\mathrm{Et}_{2} \mathrm{O}$ over $\mathrm{Na} /$ benzophenone; $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ over $\mathrm{CaH}_{2}$ ), distilled under argon and kept over $4 \AA$ A molecular sieves. All chemicals (purchased from Acros Organics or Aldrich) were of analytical grade and used as received. NMR spectra were recorded on a Bruker Avance DPX-400 instrument and referenced to deuterated solvent in the case of the ${ }^{1} \mathrm{H} N M R, \mathrm{C}_{6} \mathrm{~F}_{6}$ for the ${ }^{19} \mathrm{~F}$ NMR, $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ for ${ }^{11} \mathrm{~B}$ NMR and $\mathrm{H}_{3} \mathrm{PO}_{4}(85 \%)$ for ${ }^{31} \mathrm{P}$ NMR spectra, respectively. IR spectra were recorded on Varian FTIR - 670 spectrometer, using a GladiATR accessory with a diamond ATR element. Elemental analyses were obtained from the microanalytical laboratory in Technische Universität München. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II. Thermogravimetry analysis (TGA) was conducted utilizing a Netzsch TG209 system; typically about 10 mg of each sample were heated form $25^{\circ} \mathrm{C}$ to $1000^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Differential scanning analysis (DSC) was performed on a DSCQ2000 from TA instrument (Waters) in temperature range from $-150{ }^{\circ} \mathrm{C}$ to $200{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Melting points were measured by MPM-H2 melting point meters. TLC was performed on silica gel 60F254 plates procured form E. Merck. Silica gel ( $0.06-0.2 \mathrm{~mm} 60 \mathrm{~A}$ ) was used for column chromatography.

### 6.4.2 Synthetic method and characterization data

General procedure $\operatorname{Li}\left[B\left(\mathbf{C}_{6} \mathrm{~F}_{5}\right)_{4}\right], \quad \mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-\mathbf{3}, 5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right], \quad \mathrm{Ag}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $\mathbf{A g}$ $\left[\mathbf{B}\left(\mathbf{C}_{6} \mathbf{H}_{\mathbf{3}} \mathbf{- 3 , 5}-\left(\mathbf{C F}_{3}\right)_{2}\right)_{4}\right]$ : A 2.5 m solution of $n$-butyl lithium in $n$-hexane $(17.82 \mathrm{~mL})$ was added slowly to a solution of bromopentafluorobenzene (5 mL, 40 mmol ) or 3,5-bis(trifluoromethyl)-5-bromobenzene ( $7 \mathrm{~mL}, 40 \mathrm{mmol}$ ) in a mixture of diethyl ether ( 40 mL ) at $-78{ }^{\circ} \mathrm{C}$ and stirred for 1 h . This was followed by the dropwise addition of $\mathrm{BCl}_{3}(11.8$ $\mathrm{mL}, 11.8 \mathrm{mmol}$ ) dissolved in diethyl ether $(20 \mathrm{~mL})$. After 1 h , the resulting suspension was warmed slowly to room temperature. The product $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ or $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]$ was separated by filtration, washed with pentane several times, and then dried under vacuum
for one day. $\mathrm{Ag}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and $\mathrm{Ag}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]$ were prepared according to literature procedures. ${ }^{[14]}$
General procedure 1 for the synthesis of 1a-7a: 1 equiv $\mathrm{Li}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and 1 equiv [Cat $] \mathrm{X}$ were weighed in two different Schlenk tubes and were dissolved in a mixture $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The two solutions were mixed and stirred for 2 h at room temperature, and then filtered. The solvent is removed under high vacuum for 4 h . The product was washed with dry $n$-hexane three times and then dried in vacuum for one day.

General procedure 2 for the synthesis of 1a-7a: Equimolar amounts of $\mathrm{Ag}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]$ and [Cat]X were weighed into a Schlenk vessel. Dry $20 \mathrm{~mL} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added. The mixture was stirred in darkness at room temperature for 10 min . The precipitate was removed by filtration, and the filtrate was vacuumed for 4 h . The product was washed several times with $n$-hexane and dried in vacuum for one day.

### 6.4.3 Single-crystal X-ray structure determination

Data were collected on an X-ray single crystal diffractometer equipped with a CCD detector (Bruker APEX II, CCD), a rotating anode (Bruker AXS, FR591) with $\mathrm{MoK}_{\alpha}$ radiation ( $\lambda=$ $0.71073 \AA$ ), and a graphite monochromator by using the SMART software package. ${ }^{[30]}$ The measurements were performed on a single crystal coated with perfluorinated ether. The crystal was fixed on the top of a glass fiber and transferred to the diffractometer. The crystal was frozen under a stream of cold nitrogen. A matrix scan was used to determine the initial lattice parameters. Reflections were merged and corrected for Lorenz and polarization effects, scan speed, and background using SAINT. ${ }^{[31]}$ Absorption corrections, including odd and even ordered spherical harmonics were performed using SADABS. ${ }^{[31]}$ Space group assignments were based upon systematic absences, E statistics, and successful refinement of the structures. Structures were solved by direct methods with the aid of successive difference Fourier maps, and were refined against all data using WinGX ${ }^{[32]}$ based on SIR-92. ${ }^{[33]}$ If not mentioned otherwise, non-hydrogen atoms were refined with anisotropic displacement parameters. Methyl hydrogen atoms were refined as part of rigid rotating groups, with $\mathrm{C}-\mathrm{H}=0.98 \AA$ and Uiso( H ) $=1.5 \mathrm{Ueq}(\mathrm{C})$. Other H atoms were placed in calculated positions and refined using a riding model, with methylene and aromatic $\mathrm{C}-\mathrm{H}$ distances of 0.99 and $0.95 \AA$, respectively, and $\operatorname{Uiso}(\mathrm{H})=1.2 \cdot \operatorname{Ueq}(\mathrm{C})$. Full-matrix least-squares refinements were carried out by minimizing $\Sigma w(\mathrm{Fo} 2-\mathrm{Fc} 2) 2$ with SHELXL-97 ${ }^{[34]}$ weighting scheme. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. ${ }^{[35]}$ Images of the crystal structures were generated by PLATON. ${ }^{[36]}$ CCDC 956711 (4a), CCDC 956713 (7a), CCDC 956714 (2b) and CCDC 956712 ( $\mathbf{5 b}$ ) contains the supplementary crystallographic data for this compound. This data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif or via https://www.ccdc.cam.ac.uk/services/structure_deposit/

### 6.4.4 Catalysis studies

To a stirred solution of sulfide ( $2 \mathrm{mmol}, 0.24 \mathrm{~mL}$ ) in $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right](0.50$ mL ), an aqueous solution of hydrogen peroxide ( $30 \%$ in water) $(0.51 \mathrm{~mL}, 5 \mathrm{mmol})$ was added in 2 to 3 portions at room temperature. The progress of the reaction was followed by TLC. The reaction mixture was extracted with $n$-hexane/diethyl ether $2: 1 \mathrm{v} / \mathrm{v}(5 \times 5 \mathrm{~mL})$ and the extract was dried over anhydrous $\mathrm{MgSO}_{4}$. The crude product was obtained by rolling evaporation and purified by column chromatography separation (silica gel using $n$-hexane/ethyl acetate $90: 10 \mathrm{v} / \mathrm{v}$ ). The yield and selectivity of methyl phenyl sulfoxide in kinetic experimentand recycle experiment was calculated from calibration curves ( $r^{2}>0.999$ ) recorded using 3-methylanisole and 1,4-diacetylbenzene as internal standard. The RTIL phase was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and then treated with $\mathrm{MnO}_{2}$ to destroy the excess peroxide. The obtained liquid was dried over anhydrous $\mathrm{MgSO}_{4}$, and then dried for 4 h in vacuo at $50^{\circ} \mathrm{C}$ to remove $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Fresh substrate and hydrogen peroxide were then added for a new reaction cycle.

# 7 Oxidation reactions catalyzed by polyoxomolybdate salts 

This chapter originated from the following publication: Bo Zhang, Su Li, Alexander Pöthig, Mirza Cokoja, Shu-Liang Zang,<br>Wolfgang A. Herrmann* and Fritz E. Kühn*

Z. Naturforsch. B: J. Chem. Sci. 2013, 68(5/6), 587-597

### 7.1 Introduction

Polyoxometalates (POMs) are an important and structurally diverse class of inorganic metal oxide clusters, ${ }^{[1]}$ which are not only used as inorganic components for novel materials, but also recognized as "green" industrial catalysts. ${ }^{[2-3]}$ Recently, ionic liquids (ILs) have received enormous attention in both academic and industrial research due to their unique physicochemical properties and the resulting applicability in various fields. ${ }^{[4-10]}$ We and others have shown that certain anions exhibit an increased (catalytic) activity in ionic liquid media. ${ }^{[11-14]}$ The concept of combining POM anions with "weakly coordinating cations" (WCC), such as those typically used for ionic liquids (tetraalkyl-ammonium and -phosphonium, -pyridinium, -imidazolium and others), is thus regarded as a feasible way to increase the reactivity of POMs in ionic liquids. So far, some examples of WCC-POM compounds (e. g. $[\mathrm{Bmim}]_{3}\left[\mathrm{PW}_{12} \mathrm{O}_{40}\right]$ ( $\mathrm{Bmim}=$ 1-butyl-3-methylimidazolium), $[\mathrm{Bmim}]_{4}\left[\mathrm{SiM}_{12} \mathrm{O}_{40}\right]$ and $[\mathrm{Bmim}]_{4}\left[\mathrm{~S}_{2} \mathrm{M}_{18} \mathrm{O}_{62}\right](\mathrm{M}=\mathrm{Mo}, \mathrm{W}),\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right) \mathrm{N}\right]_{4}\left[\mathrm{Mo}_{8} \mathrm{O}_{26}\right]$ and $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right) \mathrm{N}_{2}\left[\mathrm{~W}_{6} \mathrm{O}_{19}\right]\right)$ have been described and mainly used as electrochemicals. ${ }^{[15-20]}$ However, only few POM salts have been investigated as catalysts. For example, the Keggin-type POM anion $\left[\mathrm{PW}_{12} \mathrm{O}_{40}\right]^{3-}$ can be used as catalyst for esterification ${ }^{[21]}$ and for epoxidation reactions in ionic liquids. ${ }^{[22]}$ The compound $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right) \mathrm{N}_{2}\left[\mathrm{~W}_{6} \mathrm{O}_{19}\right]\right.$ was found to be a catalyst for the synthesis of biscoumarins, which was investigated by Davoodna. ${ }^{[23]}$ From these results it appears that tungsten-based WCC-POMs can exhibit excellent catalytic performance because of controllable redox and acidic properties, ${ }^{[24-26]}$ which make them economical and environmentally acceptable. In contrast to tungsten-based WCC-POMs, which were widely used as catalysts for oxidation reactions, molybdenum-based congeners, such as the Lindqvist-type $\operatorname{POM}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$, are rather rare and have not been often used in
oxidation catalysis so far. The findings of our previous report on the catalytic oxidation of sulfides to sulfoxides using imidazolium tetrafluoroborate- and perrhenate-based ionic liquids using $\mathrm{H}_{2} \mathrm{O}_{2}{ }^{[11-14]}$ prompted us to investigate the catalytic properties of Mo-based WCC-POMs for the epoxidation of olefins and the selective oxidation of sulfides to sulfoxides.
The catalytic olefin epoxidation is of high importance in the chemical industry and also valuable for the synthesis of fine chemicals such as pharmaceuticals, flavor and fragrance components. ${ }^{[27-30]}$ A vast number of coordination compounds have been applied as catalysts for this type of reaction. ${ }^{[31-33]}$ However, the typical molecular transition metal catalysts are too expensive for a broad use and for upscaling, so that cheaper and recyclable catalysts are required. Organic sulfoxides are also important synthetic intermediates for the synthesis of various chemically and biologically active molecules. ${ }^{[34-36]}$ Numerous reports on the oxidation of sulfides to sulfoxides using homogeneous transition metal catalysts in organic solvents have been published to date. ${ }^{[37-45]}$ However, in most cases, the synthesis protocols involved formation of environmentally unfavorable byproducts, and the catalysts are rather difficult to recycle and to separate from the products. We have now found that WCC-POMs not only overcome the above mentioned drawbacks, but also can be confirmed as a good catalyst for oxidation reactions.
In this work, we present the synthesis and characterization of a series of WCC-POMs containing tetrabutylphosphonium, tributyl (tetradecyl) phosphonium, 1-butyl-3-methylimidazolium and 1,2-dimethyl-3-butyl-imidazolium cations along with the [ $\mathrm{Mo}_{6} \mathrm{O}_{19}$ ] dianion, including three X-ray single-crystal structure determinations. The WCC-POMs show high stability and selectivity for epoxidation of olefins with anhydrous urea hydrogen peroxide (UHP) as oxidant in the ionic liquid $\left[\mathrm{Bmim}^{2}\right] \mathrm{PF}_{6}$. Additionally, a highly efficient method for selective oxidation of a series of sulfides to produce the corresponding sulfoxides in excellent yield using aqueous hydrogen peroxide as oxidant and WCC-POMs as catalyst under mild reaction conditions was also investigated. The WCC-POMs can be reused several times without significant loss of activity.

### 7.2 Results and discussion

### 7.2.1 Synthesis of WCC-POMs

The WCC- $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ salts with $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}\right]^{+},\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{P}\left(n-\mathrm{C}_{14} \mathrm{H}_{29}\right)\right]^{+},[\mathrm{Bmim}]^{+}$and [Dbim] ${ }^{+}$cations were prepared by a modified literature procedure, which involves acid condensation in aqueous solution followed by addition of the precipitating cation (see Scheme 1). ${ }^{[46-48]}$ The success of the synthesis of WCC-POMs strongly depends on the pH of the reaction solution, the solvent and the temperature. The byproduct (sodium halide) can easily be removed by extraction with water. Recrystallization was performed from acetonitrile. More detailed procedures are given in the Experimental Section. All synthesized WCC-POMs are very stable and can be handled in air. They are highly soluble in $\mathrm{CH}_{3} \mathrm{CN}$, but insoluble in water and methanol.

Scheme 1. Synthesis of the WCC-POMs

### 7.2.2 Characterization of the WCC-POMs

Thermogravimetric analysis (TGA), differential scanning calorimetry (DSC) and IR spectroscopy data of compounds 1-4 are given in Table 1. TGA indicates that all compounds show negligible volatility and high thermal stability with a decomposition temperature near $300{ }^{\circ} \mathrm{C} .\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{P}\left(n-\mathrm{C}_{14} \mathrm{H}_{29}\right)\right]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]$ (2) is the only compound having a melting point below $100{ }^{\circ} \mathrm{C}\left(68{ }^{\circ} \mathrm{C}\right)$. The melting points of $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right](\mathbf{1}),[\mathrm{Bmim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right](\mathbf{3})\right.$ and $[\mathrm{Dbim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right](4)$ are 196, 128 and $193{ }^{\circ} \mathrm{C}$, respectively. Notably, the melting points of the phosphonium salts $\mathbf{1}$ and $\mathbf{2}$ decrease with increasing alkyl chain length from butyl to tetradecyl. The lower degree of crystal packing and long-range order, caused by the long alkyl chain in $\mathbf{2}$, is most presumably the reason for the significantly different melting points of compounds $\mathbf{1}$ and 2. The different melting points of compounds $\mathbf{3}$ and $\mathbf{4}$ are a consequence of the substitution of a proton in the 2-position of the imidazolium ring by a methyl group. A

## Chapter 7

comparison of the structures of compounds 3 and 4 via Hirshfeld surface analysis ${ }^{[49-50]}$ revealed that in compound 4 , the $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ anions form more attractive contacts to the cations than in compound 3 (see chapter 11 Appendix). Furthermore, the degree of hydrogen-oxygen interactions in $\mathbf{4}$ is also higher, hence leading to a higher melting point.

Table 1. Melting points ( $T_{m}$ ), decomposition temperatures ( $T_{d}$ ) and IR data of compounds 1-4.

| Compound | $T_{m}$ <br> $\left({ }^{\circ} \mathrm{C}\right)$ | $T_{d}$ <br> $\left({ }^{\circ} \mathrm{C}\right)$ |  | IR $\left(\mathrm{cm}^{-1}\right)$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

IR spectroscopy was used to identify the structure of the $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ anion. In the region of $700-1100 \mathrm{~cm}^{-1}$, four characteristic bands at around 960 and $790 \mathrm{~cm}^{-1}$ are ascribed to $v\left(\mathrm{Mo}-\mathrm{O}_{\mathrm{t}}\right)$ and $v\left(\mathrm{Mo}-\mathrm{O}_{\mathrm{b}}-\mathrm{Mo}\right)$ modes of the $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ anion $\left(\mathrm{O}_{\mathrm{t}}\right.$ and $\mathrm{O}_{\mathrm{b}}$ mark terminal and bridging oxo ligands, respectively). ${ }^{[18,51-53]}$

### 7.2.3 Crystal structures of WCC-POMs

Crystals of the new compounds $\mathbf{1 , 3}$ and $\mathbf{4}$ were grown by slow evaporation of an acetonitrile solution at room temperature. Unfortunately, we were so far not able to obtain crystals of compound $\mathbf{2}$ of a quality which is suitable for single-crystal X-ray diffraction. The structures of compounds $\mathbf{1}, \mathbf{3}$ and $\mathbf{4}$ reveal that the $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ anion consists of six distorted $\mathrm{MoO}_{6}$ octahedra, which are connected by edges and a common vertex (Figure 1). ${ }^{[54-56]}$ There are three types of oxygen atoms in the anion (terminal oxygen $\mathrm{O}_{\mathrm{t}}, \mu_{2}$-bridging oxygen $\mathrm{O}_{\mathrm{b}}$, and central oxygen $\mathrm{O}_{\mathrm{c}}$ ). Thus, the Mo-O bond lengths can be grouped into three sets (Table 2). Interestingly, the bond lengths of $\mathrm{Mo}_{\mathrm{o}} \mathrm{O}_{\mathrm{b}}(1.8740(2)-1.967(1) \AA$ ) for $\mathbf{4}$ are longer than in the WCC-POMs 1 (1.868(1)-2.002(1) $\AA$ ) and 3 (1.862(2)-2.015(2) $\AA$ ), but the bond lengths of $\mathrm{Mo}-\mathrm{O}_{\mathrm{t}}$ and $\mathrm{Mo}-\mathrm{O}_{\mathrm{c}}$ are similar. Further, a number of charge-assisted hydrogen bonds $\mathrm{CH} . . . \mathrm{O}$ exist between the cation $-\mathrm{CH}_{n}$ functions and the anion oxygen atoms of $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ (Figure 1).

Figure 1. ORTEP views of $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]\right.$ (1) (left, symmetry code: (a) $-x, y, 1 / 2-z$ ), $[\mathrm{Bmim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]$ (3) (middle, symmetry code: (a) $-x, y+1 / 2,1 / 2-z$ ) and [Dbim $]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]$ (4) (right, symmetry code: (a) $1 / 2-x, y+1 / 2,1 / 2-z$ ) showing vibrational ellipsoids at the $50 \%$ probability level. H atoms are omitted for clarity.

Table 2. Selected bond lengths ( $\AA$ ) of $\mathbf{1 , 3}$ and 4.

|  | $\mathbf{1}$ | $\mathbf{3}$ | $\mathbf{4}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{Mo}-\mathrm{O}_{\mathrm{t}}$ | $1.672(2)-1.688(1)$ | $1.678(2)-1.68(2)$ | $1.6780(3)-1.686(1)$ |
| $\mathrm{Mo}-\mathrm{O}_{\mathrm{b}}$ | $1.868(1)-2.002(1)$ | $1.862(2)-2.015(2)$ | $1.8740(2)-1.967(1)$ |
| $\mathrm{Mo}_{\mathrm{c}}$ | $2.313(2)-2.319(1)$ | $2.318(1)-2.329(1)$ | $2.3157(3)-2.324(1)$ |

Each polyoxoanion is surrounded by $\left.\left[\left(\mathrm{n}-\mathrm{C}_{4} \mathrm{H}_{9}\right)\right)_{4} \mathrm{P}\right]^{+},[\mathrm{Bmim}]^{+}$or $[\mathrm{Dbim}]^{+}$cations, respectively, exhibiting H...O distances in the range of 2.254 to $2.680(\AA)$ for $\mathbf{1}, 2.493$ to $2.665(\AA)$ for 3 and 2.358 to $2.680(\AA)$ for $\mathbf{4}$, which indicate interactions between the polyoxoanions and cations via Coulomb forces and CH...O hydrogen bonds. For compound 1, contacts between the $\mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$ groups of the butyl moieties and the $\mathrm{O}\left(\mathrm{O}_{\mathrm{t}}, \mathrm{O}_{\mathrm{b}}\right)$ atoms of $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ can be observed. Compounds $\mathbf{3}$ and $\mathbf{4}$ also exhibit contacts between the anion and the imidazolium ring hydrogen atoms and the alkyl substituents of the cation.

### 7.2.4 Catalytic epoxidation of olefins

Compounds 1-4 were examined as catalysts for the epoxidation of cis-cyclooctene. The organic and ionic liquid solvents, as well as the oxidants were varied in order to determine the optimal reaction conditions (Table 3). The epoxide yield was indeed found to be strongly dependent on these parameters. Noteworthy, the (usually undesired) byproduct 1,2 -cyclooctane diol was not found in the entire set of experiments. The observed conversion was very low ( $<30 \%$ ) with $\mathrm{CH}_{3} \mathrm{CN}$ and $[\mathrm{Bmim}] \mathrm{BF}_{4}$ as solvents (entries 1-2 and 4-6). On the other hand, when the reaction was carried out in methanol and in the ionic liquids [ Bmim ] $\mathrm{PF}_{6}$ and $[\mathrm{Bmim}] \mathrm{NTf}_{2}\left(\mathrm{NTf}_{2}=\operatorname{bis}(\right.$ trifluoromethylsulfonyl)imide) as solvents, the epoxide yield was significantly higher (entries 3, 7-9 and 11-13). The nature of the oxidant also plays a crucial role in the reaction. Three different oxidants (aqueous $\mathrm{H}_{2} \mathrm{O}_{2}$, tert-butyl hydroperoxide (TBHP) in $n$-decane and urea-hydrogen peroxide (UHP)) were examined under the same

## Chapter 7

conditions. From the results shown in Table 3, entries 7-13, it can be stated that a) aqueous hydrogen peroxide solutions inhibit the catalytic reaction to some extent, and b) UHP is superior to both TBHP and $\mathrm{H}_{2} \mathrm{O}_{2}$. Obviously, the olefin conversion significantly depends on the content of water in the solution. The catalytic reaction in ionic liquid [ Bmim$] \mathrm{PF}_{6}$ with UHP exhibited both a high yield of $89 \%$ and a selectivity of $>99 \%$ within 4 h (entry 9). Therefore, the usage of water-free UHP is crucial for successful epoxidation. Furthermore, in the blank experiments, no reaction occurred in the absence of oxidant UHP, indicating that the oxygen source of epoxides is not air (entry 10). Epoxidation of cis-cyclooctene at different temperatures was investigated as well. The reaction conditions were the same as those of entry 9 in Table 3.

Table 3. Epoxidation of cis-cyclooctene in different oxidants and solvents at $60^{\circ} \mathrm{C}$ using WCC-POM 1 as catalyst. ${ }^{\text {a }}$

| 13 | [Bmim] $\mathrm{NTf}_{2}$ | UHP | 63 | 63 |

${ }^{\text {a }}$ Reaction conditions: cis-cyclooctene ( 2 mmol ), catalyst $\mathbf{1}(1 \mathrm{~mol} \%)$, oxidant ( 4 mmol ), solvent $(1 \mathrm{~mL})$, $60^{\circ} \mathrm{C}, \mathrm{t}=4 \mathrm{~h}$;
${ }^{\mathrm{b}}$ The conversion to cyclooctene oxide was determined by GC analysis;
${ }^{\mathrm{c}}$ The yield was determined by GC analysis.
As indicated in Figure 2, a lower temperature was disadvantageous to the oxidation reaction. The yield was only $69 \%$ within 4 h , and $72 \%$ after 24 h at $50^{\circ} \mathrm{C}$. Because of the high yield $\left(93 \%\right.$ within $4 \mathrm{~h}, 97 \%$ after 24 h ) at $70^{\circ} \mathrm{C}$, we chose $70^{\circ} \mathrm{C}$ as reaction temperature for further experiments.

Figure 2. Effect of temperature and reaction time for the catalytic epoxidation of cis-cyclooctene with compound $\mathbf{1}$ as catalyst. Reaction conditions: cis-cyclooctene ( 2 mmol ), catalyst $\mathbf{1}$ ( $1 \mathrm{~mol} \%$ ), UHP $(4 \mathrm{mmol}),[\mathrm{Bmim}] \mathrm{PF}_{6}(1 \mathrm{~mL})$.

Subsequently, in a comparative study the other synthesized WCC-POMs 2-4 were also used as catalysts in the epoxidation of cis-cyclooctene with UHP at $70{ }^{\circ} \mathrm{C}$ for 2 h . The results are shown in Table 4. Compound 3 exhibits the highest reactivity and conversion for the epoxidation of cis-cyclooctene (entry 3), most presumably due to the highest solubility in $[B m i m] \mathrm{PF}_{6}$ at $70^{\circ} \mathrm{C}$. The other catalysts $\mathbf{1 , 2}$ and $\mathbf{4}$ also exhibited good results and the yields were $93 \%, 90 \%$ and $94 \%$, respectively (entries 1-2, 4).

Table 4. Epoxidation of cis-cyclooctene with different catalysts in $[\mathrm{Bmim}] \mathrm{PF}_{6}$ at $70{ }^{\circ} \mathrm{C}$. ${ }^{\text {a }}$

| Entry | Catalyst | Conv. $(\%)^{\text {b }}$ | Yield (\%) | TOF $\left(\mathrm{h}^{-1}\right)^{\mathrm{d}}$ |

| 4 | $\mathbf{4}$ | 94 | 94 | 47 |

${ }^{\mathrm{a}}$ Reaction conditions: cis-cyclooctene ( 2 mmol ), catalyst ( $1 \mathrm{~mol} \%$ ), UHP ( 4 mmol ), $[\mathrm{Bmim}] \mathrm{PF}_{6}(1 \mathrm{~mL})$, $70^{\circ} \mathrm{C}, \mathrm{t}=2 \mathrm{~h}$;
${ }^{\mathrm{b}}$ The conversion is determined by GC analysis;
${ }^{\mathrm{c}}$ The yield is determined by GC analysis;
${ }^{\mathrm{d}}$ Determined after 2 h reaction time.
WCC-POM catalyst recycling was studied as well. First, the product was extracted with $n$-hexane and the ionic liquid phase containing the catalyst was washed with water to remove urea ([Bmim $] \mathrm{PF}_{6}$ and $\mathrm{WCC}-\mathrm{POMs}$ are insoluble in water). The IL was then dried in high vacuum and used for the next catalytic run. The WCC-POMs remained active for at least three catalytic runs. However, a slight decrease of conversion and yield was observed (Figure 3). Most presumably, this is resulting from the workup procedure, since the IL-catalyst solution is washed several times with $n$-hexane and there after with water. Hence, it is reasonable to assume that phase separation and subsequent decantation of the $n$-hexane and water phase

## Chapter 7

might have led to unintentional extraction of small amounts of the IL.

Figure 3. Recycling studies of the IL-catalyst mixture for the epoxidation of cis-cyclooctene.
Catalyst 3 was applied for the epoxidation of various olefins with UHP as oxidant (Table 5). Cyclohexene was readily epoxidized into the epoxide within 1.5 h with $88 \%$ yield (entry 2 ). Only moderate conversion ( $46 \%$ ) was observed for 1-octene (entry 3 ), which is less prone to epoxidation than cis-cyclooctene. The epoxidations of trans- $\beta$-methylstyrene (entry 4), limonene (entry 5), cis-stilbene (entry 6) and (+)-camphene (entry 7) were rather challenging due to steric hindrance ( $26 \%$ after $3 \mathrm{~h}, 24 \%$ after $7 \mathrm{~h}, 25 \%$ after $4 \mathrm{~h}, 9 \%$ after 8 h , respectively). The turnover frequencies (TOFs) are in the range of $16-182 \mathrm{~h}^{-1}$. It is noteworthy that no diol is detected during the course of all investigated reactions.

Table 5. Epoxidation of olefins with UHP catalyzed by 3 at $70^{\circ} \mathrm{C}$. ${ }^{\text {a }}$

${ }^{\mathrm{a}}$ Reaction conditions: cis-cyclooctene ( 2 mmol ), $\mathbf{3}(1 \mathrm{~mol} \%)$, UHP ( 4 mmol ), $[\mathrm{Bmim}] \mathrm{PF}_{6}(1 \mathrm{~mL}), 70{ }^{\circ} \mathrm{C}$;
${ }^{\mathrm{b}}$ The conversion is determined by GC analysis;
${ }^{\mathrm{c}}$ The yield is determined by GC analysis;
${ }^{\mathrm{d}}$ Determined after 15 min reaction time.

### 7.2.5 Selective catalytic oxidation of sulfides to sulfoxides

We investigated the oxidation reaction of thioanisole as model substrate in different oxidants and solvents. The results are presented in Table 6 and showed that the reaction was sensitive to the solvent. When using $n$-hexane (entry 1 ), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (entry 2) and water (entry 4) as solvents, very low conversions and yields were obtained due to the poor solubility of the catalyst in these solvents. When the reaction was carried out in acetonitrile (entry 3), high conversion ( $97 \%$ ) and yield ( $82 \%$ ) were obtained within 40 min , but the selectivity of sulfoxide was relatively lower than when using methanol, which was found to be a more efficient reaction medium ( $95 \%$ yield, $97 \%$ conversion, entry 5). Note that methanol itself
can act as catalyst of the oxidation of thioanisol. ${ }^{[57-59]}$ However, the reaction time is usually significantly longer ( 18 h ), whereas in our experiments using catalyst $\mathbf{3}$ as catalyst in methanol, high conversion ( $97 \%$ ) was obtained after 40 min (entry 5). In the blank experiment, the conversion was only $41 \%$ without any catalyst (entry 9 ).

Table 6. Oxidation of thioanisole with different oxidants in different solvents at $25^{\circ} \mathrm{C}$. ${ }^{\text {a }}$

| Entry | Solvent | Oxidant | Time (h) | Conv. (\%) | Yield (\%) ${ }^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $n$-hexane | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 4 | 82 | 57 |
| 2 | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 4 | 16 | 14 |
| 3 | $\mathrm{CH}_{3} \mathrm{CN}$ | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 0.67 | 97 | 82 |
| 4 | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 4 | 80 | 67 |
| $\mathbf{5}$ | $\mathbf{M e O H}$ | $\mathbf{H}_{2} \mathbf{O}_{\mathbf{2}}(\mathbf{3 5} \%)$ | $\mathbf{0 . 6 7}$ | $\mathbf{9 7}$ | $\mathbf{9 5}$ |
| 6 | MeOH | TBHP | 3 | 73 | 71 |
| 7 | MeOH | ---- | 24 | 28 | 27 |
| 8 | ----- | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 4 | 93 | 46 |
| 9 | MeOH | $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ | 8 | $52^{\mathrm{d}}$ | 41 |

${ }^{\mathrm{a}}$ Reaction conditions: thioanisole ( 2 mmol ), $\mathbf{3}(1 \mathrm{~mol} \%), \mathrm{H}_{2} \mathrm{O}_{2}(35 \%, 2.1 \mathrm{mmol})$, solvent $(1 \mathrm{~mL}) 25{ }^{\circ} \mathrm{C}$;
${ }^{\mathrm{b}}$ Determined by GC on the crude reaction mixture;
${ }^{\text {c }}$ Isolated yield after column chromatography.
Thus, it can safely be concluded that methanol is not catalyzing the oxidation in our case. The absence of oxidant leads to a significant decrease of conversion ( $28 \%$, entry 7). An obvious decrease of oxidation activity was observed by adding TBHP as oxidant (entry 6). The yield decreased to $46 \%$ after 4 h without any solvent (entry 8 ).
In an effort to establish the scope of our protocol, a series of sulfides with different substituents were used (Scheme 2) in methanol. All oxidation reactions were performed under the same conditions (Table 7) and showed nearly quantitative conversions within a very short time (< 3 h ). The sulfoxides were obtained in very good selectivities (> $80 \%$ ), as well as TOFs were in the range of $165-380 \mathrm{~h}^{-1}$.

Scheme 2. Oxidation of sulfides to sulfoxides with aqueous hydrogen peroxide as oxidant and
$[\mathrm{Bmim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]$ (3) as catalyst in methanol.
Interestingly, sulfides with methyl groups (entry 1) were found to be more easily oxidized within short time (ca. 30 min ) compared to other substrates with bulky substituents, indicating that the steric hindrance is an important factor for the oxidation reaction. It was a significant observation that functional groups such as allyl (entry 6), hydroxo (entry 7) and ester moieties (entry 9) were not affected in this oxidation procedure. Noteworthy, the WCC-POM catalyst 3 was very easily recovered by filtration when the reaction was completed. Therefore, the

## Chapter 7

WCC-POMs $-\mathrm{H}_{2} \mathrm{O}_{2}$ system offered a facile, rapid, highly selective method to obtain sulfoxides.

${ }^{\mathrm{e}}$ TOFs of the catalyst were calculated over 30 min ;
${ }^{\mathrm{f}} \mathrm{Bz}=$ benzyl.
The reusability of the catalyst WCC-POMs for oxidation of sulfides to sulfoxides was also studied. After the oxidation of thioanisole using $\mathbf{3}$ as catalyst was completed, ethyl acetate was added to the reaction mixture and the catalyst was precipitated, filtered, washed with ethyl acetate, and dried in vacuum at room temperature. Five catalytic runs were carried out and the results are shown in Figure 4. It has to be noted that no significant loss of conversion and yield was observed after five runs, indicating a rather steady reusability of the WCC-POM catalyst. In comparison to the recycling of the IL-catalyst mixture for the epoxidation of olefins, in this case the catalyst precipitation is a more convenient method to recover the catalyst without a loss after each cycle.

Figure 4. Recycling of the catalyst $\mathbf{3}$ in the oxidation of thioanisole with $\mathrm{H}_{2} \mathrm{O}_{2}$.

### 7.3 Conclusion

The epoxidation of olefins and oxidation of sulfides to sulfoxides catalyzed by polyoxomolybdate salts containing weakly coordinating cations was achieved under mild conditions. The preparation of the catalysts is simple and convenient, and they can be recycled several times. The WCC-POM catalysts show high stability and selectivity for the epoxidation of olefins in ionic liquid $[\mathrm{Bmim}] \mathrm{PF}_{6}$ with anhydrous urea hydrogen peroxide (UHP) as oxidant. A method for the selective oxidation of sulfides to the corresponding sulfoxides using aqueous hydrogen peroxide as oxidant has also been developed. It is note that both catalytic reactions are cost-efficient.

### 7.4 Experimental section

### 7.4.1 General

All reactions were performed using standard Schlenk techniques under an argon atmosphere. All solvents were collected from purification systems and kept over molecular sieves. ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and ${ }^{31} \mathrm{P}$ NMR spectrawere recorded on a Bruker Avance DPX-400 spectrometer and referenced to deuterated solvent in the case of the ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR, $\mathrm{C}_{6} \mathrm{~F}_{6}$ for the ${ }^{19} \mathrm{~F}$ NMR, $\mathrm{H}_{3} \mathrm{PO}_{4}(85 \%)$ for ${ }^{31} \mathrm{P}$ NMR, respectivitly. IR spectra were recorded on a Varian FTIR-670 spectrometer, using a GladiATR accessory with a diamond ATR element. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II. Elemental analyses were performed with a Flash EA 1112
series elemental analyzer.Thermogravimetric (TG) and differential scanning (DSC) analysis was conducted utilizing a Netzsch-STA 409 PC system. Typically about 10 mg of each sample was heated from 25 to $1000{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Melting points were determined by MPM-H2 melting point meters. TLC was performed on silica gel 60 F 254 plates procured form E. Merck. Silica gel ( $0.06-0.2 \mathrm{~mm} 60 \mathrm{~A}$ ) was used for column chromatography. All chemicals were purchased from Acros and ABCR and used without further purification. $[\mathrm{Bmim}] \mathrm{PF}_{6},[\mathrm{Bmim}] \mathrm{BF}_{4}$ and $[\mathrm{Bmim}] \mathrm{NTf}_{2}$ were synthesized according to literature procedures. ${ }^{[60-61]}$

### 7.4.2 Synthetic method and characterization data

Synthesis of $\left[\left(\mathbf{n}-\mathbf{C}_{\mathbf{4}} \mathbf{H}_{\mathbf{9}}\right)_{\mathbf{4}} \mathbf{P}\right]_{\mathbf{2}}\left[\mathbf{M o}_{\mathbf{6}} \mathbf{O}_{\mathbf{1 9}}\right](\mathbf{1}): \mathrm{Na}_{2} \mathrm{MoO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}(4.8 \mathrm{~g}, 20 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was mixed with acetonitrile, and $\mathrm{HCl}(37 \%, 10 \mathrm{~mL})$ was added. The resulting mixture was refluxed for 1 h . After cooling, the lower aqueous layer was discarded and the upper layer was treated with $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}\right] \mathrm{Br}(2.7 \mathrm{~g}, 10.4 \mathrm{mmol})$ in water $(100 \mathrm{~mL})$. The precipitate was filtered and thoroughly washed successively three times with water and ethanol. Recrystallization of the solid from acetonitrile afforded yellow crystals of $\left[\left(\mathrm{n}-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}\right]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]$-DMSO, r. t., ppm): $\delta=0.93(\mathrm{~d}, 12 \mathrm{H}), 1.42$ $(\mathrm{m}, 16 \mathrm{H}), 2.19(\mathrm{~m}, 8 \mathrm{H}) ;{ }^{31} \mathrm{P}$ NMR ( $162 \mathrm{MHz},\left[\mathrm{D}_{6}\right]$-DMSO, r. t., ppm): $\delta=33.78$; Elemental analysis (\%): calcd. C 27.48, H 5.19; found C 27.55, H 5.20; IR (cm ${ }^{-1}$ ): $v=434.9(\mathrm{~s}), 594.8$ (m), 720.6 (m), 920.2 (w), 949.0 (vs), $1003.8(\mathrm{w}), 1100.9$ (w), 1085.4 (w), 1378.8 (w), 1462.5 (w), 1919.5 (w), 2157.9 (w), 2871.1 (w), 2929.5 (w), 2959.6 (w).

Synthesis of $\left[\left(\mathbf{n}-\mathbf{C}_{\mathbf{4}} \mathbf{H}_{\mathbf{9}}\right)_{\mathbf{3}} \mathbf{P}\left(\mathbf{n}-\mathbf{C}_{\mathbf{1 4}} \mathbf{H}_{\mathbf{2 9}}\right)\right]_{\mathbf{2}}\left[\mathbf{M o}_{\mathbf{6}} \mathbf{O}_{\mathbf{1 9}}\right]$ (2): $\mathrm{Na}_{2} \mathbf{M o O}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}(4.8 \mathrm{~g}, 20 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was mixed with acetonitrile, and $\mathrm{HCl}(37 \%, 10 \mathrm{~mL})$ was added. The resulting mixture was refluxed for 1 h . After cooling, the lower aqueous layer was discarded and the upper layer was treated with $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{P}\left(n-\mathrm{C}_{14} \mathrm{H}_{29}\right)\right] \mathrm{Cl}(4.99 \mathrm{~g}, 10.4 \mathrm{mmol})$ in water ( 100 mL ). The precipitate was filtered and thoroughly washed successively three times with water and ethanol. Recrystallization of the solid from acetonitrile afforded pale-green crystals of $\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{P}\left(n-\mathrm{C}_{14} \mathrm{H}_{29}\right)\right]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right] .{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]-\mathrm{DMSO}\right.$, r. t., ppm): $\delta=0.89(\mathrm{~d}$, $3 \mathrm{H}), 1.00(\mathrm{~d}, 9 \mathrm{H}), 1.29(\mathrm{~m}, 18 \mathrm{H}), 1.39(\mathrm{~d}, 2 \mathrm{H}), 1.56(\mathrm{~m}, 8 \mathrm{H}), 1.70(\mathrm{~m}, 8 \mathrm{H}), 2.40(\mathrm{~m}, 8 \mathrm{H}) ;{ }^{31} \mathrm{P}$ NMR (162 MHz, [D $\mathrm{D}_{6}$ ]-DMSO, r. t., ppm): $\delta=33.95$; Elemental analysis (\%): calcd. Synthesis of $[\mathbf{B m i m}]_{2}\left[\mathbf{M o}_{6} \mathbf{O}_{\mathbf{1 9}}\right]$ (3): $\mathrm{Na}_{2} \mathrm{MoO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}(4.8 \mathrm{~g}, 20 \mathrm{mmol})$ was dissolved into 10 $\mathrm{mL} \mathrm{H}_{2} \mathrm{O}$, and an aqueous solution of $\mathrm{HCl}(37 \%, 5 \mathrm{~mL})$ was added. After stirring for 10 min ,
$[\mathrm{Bmim}] \mathrm{Br}(1.6 \mathrm{~g}, 3.75 \mathrm{mmol})$ was added with vigorous stirring. The precipitate was filtered and thoroughly washed successively three times with water and ethanol. Recrystallization of the solid from acetonitrile afforded yellow crystals of $[\mathrm{Bmim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right] .{ }^{1} \mathrm{H}$ NMR ( 400 MHz , [ $\left.\mathrm{D}_{6}\right]$-DMSO, r. t., ppm): $\delta=0.91(\mathrm{~d}, 3 \mathrm{H}), 1.27(\mathrm{~m}, 2 \mathrm{H}), 1.78(\mathrm{~m}, 2 \mathrm{H}), 3.87(\mathrm{~s}, 3 \mathrm{H}), 4.17(\mathrm{t}$, $2 \mathrm{H}), 7.69(\mathrm{~s}, 1 \mathrm{H}), 7.75(\mathrm{~s}, 1 \mathrm{H}), 9.10(\mathrm{~s}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz},\left[\mathrm{D}_{6}\right]$-DMSO, r. t., ppm): $\delta$ $=13.76,19.28,31.87,36.23,49.04,122.70,124.08,136.95$; Elemental analysis (\%): calcd. C 16.57, H 2.78, N 4.83; found C 16.69, H 2.61, N 4.64; IR $\left(\mathrm{cm}^{-1}\right): v=437.1(\mathrm{~m}), 614.5(\mathrm{~m})$, 753.6 ( s ), 786.2 (vs), 878.6 (w), 911.8 (m), 952.3 (vs), 1164.3 (m), 1462.0 (w), 1568.3 (w), 1906.3 (w), 2870.2 (w), 2930.9 (w), 2959.3 (w), 3115.6 (w), 3144.8 (w).

Synthesis of [Dbim] $]_{2}\left[\mathbf{M o}_{6} \mathbf{O}_{\mathbf{1 9}}\right.$ ] (4): $\mathrm{Na}_{2} \mathrm{MoO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}(4.8 \mathrm{~g}, 20 \mathrm{mmol})$ was dissolved in 10 $\mathrm{mL} \mathrm{H}_{2} \mathrm{O}$, and an aqueous solution of $\mathrm{HCl}(37 \%, 5 \mathrm{~mL})$ was added. After stirring for 10 min , [Dbim] $\operatorname{Br}(1.75 \mathrm{~g}, 3.75 \mathrm{mmol})$ was added with vigorous stirring. The precipitate was filtered and thoroughly washed successively three times with water and ethanol. Recrystallization of the solid from acetonitrile afforded pale-yellow crystals of [Dbim] $]_{2} \mathrm{Mo}_{6} \mathrm{O}_{19}$. ${ }^{1} \mathrm{H}$ NMR (400 $\mathrm{MHz},\left[\mathrm{D}_{6}\right]$-DMSO, r. t., ppm): $\delta=0.92(\mathrm{t}, 3 \mathrm{H}), 1.29(\mathrm{~m}, 2 \mathrm{H}), 1.70(\mathrm{~m}, 2 \mathrm{H}), 2.59(\mathrm{~s}, 3 \mathrm{H}), 3.76$ $(\mathrm{s}, 3 \mathrm{H}), 4.11(\mathrm{t}, 2 \mathrm{H}), 7.61(\mathrm{~s}, 1 \mathrm{H}), 7.64(\mathrm{~s}, 1 \mathrm{H}),{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz},\left[\mathrm{D}_{6}\right]-\mathrm{DMSO}$, r. t., ppm): $\delta=9.60,13.87,19.37,31.64,35.14,47.79,121.32,122.78,144.64$; Elemental analysis (\%): calcd. C 18.20, H 3.05, N 4.72; found C 18.14, H 2.94, N 4.65; IR ( $\mathrm{cm}^{-1}$ ): $v=434.3$ (s), 592.2 (s), 753.7 ( s), 787.0 (vs), 948.6 (vs), 1093.2 (w), 1133.9 (w), 1247.0 (w), 1417.3 (w), 15334.6 (w), 1588.1 (w), 1901.0 (w), 2962.2 (w), 3140.6 (w).

### 7.4.3 Single-crystal X-ray structure determination

The data were collected on an X-ray diffractometer equipped with a CCD detector (APEX II, $\kappa$-CCD), a rotating anode (Bruker AXS, FR591) or a fine-focused sealed tube with Mo- $K_{\alpha}$ radiation ( $\lambda=0.71073 \AA$ ), and a graphite monochromator by using the SMART software package. ${ }^{[62]}$ The measurements were performed on single crystals coated with Paratone oil and mounted on glass capillaries. Each crystal was frozen under a stream of nitrogen. A matrix scan using at least 20 centered reflections was used to determine the initial lattice parameters. Reflections were merged and corrected for Lorentz and polarization effects, scan speed, and background using SAINT 4.15. ${ }^{[63]}$ Absorption corrections, including odd and even ordered spherical harmonics were performed using SADABS. ${ }^{[63]}$ Space group assignments were based upon systematic absences, E statistics, and successful refinement of the structures. Structures were solved using Bruker APEX suite, ${ }^{[64]}$ and were refined against all data using Shelxle. ${ }^{[65]}$ Hydrogen atoms were assigned to ideal positions and refined using a riding
model with an isotropic thermal parameter 1.2 times that of the attached carbon atom (1.5 times for methyl hydrogen atoms). If not mentioned otherwise, non-hydrogen atoms were refined with anisotropic displacement parameters. Full-matrix least-squares refinements were carried out by minimizing $\Sigma w\left(F_{o}{ }^{2}-F_{c}{ }^{2}\right)^{2}$ with the SHELXL-97 weighting scheme. ${ }^{[66]}$ Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. ${ }^{[67]}$ Images of the crystal structures were generated by PLATON ${ }^{[68]}$ and Mercury. ${ }^{[69]}$

(No. 14), $\quad a=11.0074(2), \quad b=10.7827(2), \quad c=13.5900(3) \AA, \quad \beta=91.045(1)^{\circ}, \quad V=$ $1612.72(5) \AA^{3}, Z=2, \lambda\left(\mathrm{Mo}-K_{\alpha}\right)=0.71073 \AA, \mu=2.347 \mathrm{~mm}^{-1}, \rho_{\text {calcd }}=2.44 \mathrm{~g} \mathrm{~cm}^{-3}, T=123$ (1) $\mathrm{K}, F(000)=1148, \theta_{\max }=25.47^{\circ}, R_{l}=0.0256$ (2902 observed data), $w R_{2}=0.0660$ (all 2989 data), $\mathrm{GOF}=1.161,218$ parameters, $\Delta \rho_{\max } / \min =1.36 /-0.58 \mathrm{e} \cdot \AA^{-3}$. For more detailed information see Appendix.
Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with The Cambridge Crystallographic Data Centre as supplementary publication Nr. CCDC-892238 ( $\left[\left(\mathrm{n}-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{P}_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]\right)$, CCDC-892239 ( $\left.[\mathrm{Bmim}]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]\right)$, and CCDC-892240 ([Dbim $\left.]_{2}\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]\right)$. Copies of the data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cifs.

### 7.4.4 General procedure for the epoxidation of olefins

In a typical reaction, the catalyst ( $20 \mu \mathrm{~mol}$ ) was dissolved in solvent ( 1 mL ). Substrate ( 2 mmol ) was added, followed by the addition of UHP ( $4 \mathrm{mmol}, 0.3762 \mathrm{~g}$ ). The reaction mixture was extracted with $n$-hexane ( $5 \times 1 \mathrm{~mL}$ ) and then monitored by quantitative GC analysis. Samples were taken at regular time intervals. The resulting slurry was filtered and the filtrate
injected onto a GC column. The conversion of olefins and the formation of epoxides were calculated from calibration curves $\left(r^{2}>0.999\right)$ recorded prior to the reaction. For the recycling experiment, 3 mL of water was added to the mixtures after extractingsubstrate and product with $n$-hexane. The upper phasewas removed from the reaction by means of cannulation. The IL phase was washed three times with water and then dried in vacuum for 4 h . Fresh substrate and UHP were then added for a new reaction cycle.

### 7.4.5 General procedure for the oxidation of sulfides

Catalyst ( $20 \mu \mathrm{~mol}$ ) and 2 mmol of sulfide ( 2 mmol ) were dissolved in $\mathrm{MeOH}(1 \mathrm{~mL}$ ), followed by dropwise adding $\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)(0.19 \mathrm{~mL}, 2.1 \mathrm{mmol})$ at room temperature. The progress of the reaction was followed by TLC. After completion of the reaction, 3 mL of ethyl acetate was added to the mixture to obtain the catalyst by filtration. The solvent was removed under vacuum for 4 h and then the crude products were analyzed by GC or ${ }^{1} \mathrm{H}$ NMR using internal standard technology. The sulfoxides were purified by column chromatography (silica gel using hexane/ethyl acetate $90: 10 \mathrm{v} / \mathrm{v}$ ). For the recycling experiment, ethyl acetate was added to the reaction mixture after the reaction was completed and the catalyst precipitated, filtered off, washed with ethyl acetate, and dried in high vacuum at room temperature.

# 8 Schiff base complexes of methyltrioxorhenium (VII): synthesis and catalytic application 

This chapter originated from the following publication:<br>Bo Zhang, Su Li, Eberhardt Herdtweck and Fritz E. Kühn*

J. Organomet. Chem. 2013, 739, 63-68.

### 8.1 Introduction

Epoxides are valuable intermediates in organic chemistry, for fine chemicals and in pharmaceutical synthesis. ${ }^{[1-3]}$ A broad variety of catalysts for olefin epoxidation has been described. ${ }^{[4-7]}$ Among these catalysts, methyltrioxorhenium (VII) $\left(\mathrm{MeReO}_{3}, \mathrm{MTO}\right)$ was found to be one of the most efficient and powerful for olefin epoxidation when employing hydrogen peroxide as oxidant. ${ }^{[8-13]}$ However, due to the pronounced Lewis acidity of MTO and in the presence of water (formed as by-product from hydrogen peroxide) ring opening of the epoxides to diols often takes place, particularly when more sensitive epoxides are formed. ${ }^{[8-9]}$ Several methods have been suggested to overcome this problem. An efficient procedure developed to avoid this side reaction requires the use of urea hydrogen peroxide adduct (UHP) as oxidant, which enables epoxidation to be carried out in non-aqueous media. ${ }^{[14-15]}$ Another method is the application of excess aromatic N -bases, ligating the Re center in an equilibrium reaction and thereby reducing the Lewis acidity of the catalyst and accelerating the catalytic reaction additionally. ${ }^{[16-21]}$

However, separation of the catalyst, containing the expensive element rhenium is an additional issue. Two-phase reactions are often chosen to achieve this purpose. Among such solvents non-volatile ionic liquids (ILs) have received a great deal of attention in recent years due to their unique properties. ${ }^{[22-25]}$ It has already been noted that some Schiff base adducts of MTO display high catalytic activity in organic solvent. ${ }^{[26-30]}$ With the aim of developing more sustainable procedures for olefin epoxidation, Schiff base adducts of MTO are combined with ILs as solvent and UHP as oxidant.

### 8.2 Results and discussion

### 8.2.1 Synthesis and spectroscopic characterization

Complexes 1-4 (Scheme 1) were synthesized by treatment of MTO with the respective Schiff bases in diethyl ether at room temperature, while complexes $\mathbf{5 - 8}$ were prepared in methanol. The product formation can be easily followed due to the appearance of orange-yellow color. The product can be purified by re-crystallization from $\mathrm{Et}_{2} \mathrm{O} / n$-hexane or methanol. In comparison to many N -coordinated Lewis base adducts, being considerably less stable against moisture and temperature than MTO itself, ${ }^{[31-33]}$ complexes $\mathbf{1 - 8}$ show good stability in air at room temperature for several days and can be handled without decomposition.

 $\mathbf{R}=\mathbf{H}, \mathbf{R}^{\prime}=(\mathbf{R})$-(+)-alpha-methylbenzyl (4)

R = (s)-(-)-alpha-methylbenzyl (5), (s)-(-)-1-phenylpropyl(6), (R)-(+)-alpha-methylbenzyl (7), (s)-1-(4-chlorophenyl)ethyl (8)

Scheme 1. Synthesis of MTO complexes1-8
In the IR spectra of complexes $\mathbf{1 - 8}$, the asymmetric $\mathrm{Re}=\mathrm{O}$ stretching vibrations are observed in the region of $910-965 \mathrm{~cm}^{-1}$, while the symmetric $\mathrm{Re}=\mathrm{O}$ stretching vibrations are found between 1027 and $934 \mathrm{~cm}^{-1}$ (See Table 1). It is seen that in comparison to the asymmetric stretching vibrations exhibited by non-coordinated MTO ( $v_{\text {sym }}=998 \mathrm{~cm}^{-1}, v_{\text {asym }}=965 \mathrm{~cm}^{-1}$ ), the respective $\mathrm{Re}=\mathrm{O}$ bands of complexes $\mathbf{1 - 8}$ are strongly shifted. This vibration differences reflect the donor capacity of the Schiff base ligands, reducing the bond order of the $\mathrm{Re}=\mathrm{O}$ bonds.
For free MTO the difference between $v_{\text {sym }}(\operatorname{Re}=\mathrm{O})$ and $v_{\text {asym }}(\operatorname{Re}=\mathrm{O})$ is $33 \mathrm{~cm}^{-1}$ (tetrahedral
coordination geometry). Complexes 1-4 and 5-8, the difference between the symmetric and asymmetric $\mathrm{Re}=\mathrm{O}$ stretching vibrations is not equally large, indicating different coordination geometries of Re center. It is $65.5-93 \mathrm{~cm}^{-1}$ for complexes $\mathbf{1 - 4}$ and $24-32 \mathrm{~cm}^{-1}$ for the complexes 5-8. It has been reported that differences of $20-27$ and $60-80 \mathrm{~cm}^{-1}$ between $v_{\text {sym }}$ $(\operatorname{Re}=\mathrm{O})$ and $v_{\text {asym }}(\mathrm{Re}=\mathrm{O})$ correspond to octahedral and trigonal-bipyramidal coordination geometry, respectively. ${ }^{[29-30]}$ In some special cases, the differences can become very large (167 $\mathrm{cm}^{-1}$ ) due to the rather asymmetric coordination of the rhenium atom. ${ }^{[26]}$ Therefore, it can be deduced that the complexes 1-4 are closer to trigonal-bipyramidal coordination geometry, while complexes 5-8 have a (slightly distorted) octahedral geometry. Additionally, the stretching vibrations of the iminic bands in the complexes 1-8 are also significantly shifted when compared to the free ligands (see below).

Table 1. Selected IR spectroscopic data of Schiff-bases and MTO adducts.

| Compound | Imine | $\mathrm{ReO}_{3}$ |  |  |
| :---: | :---: | :---: | :---: | :---: |

| C8 | 1640 | 945 | 913 | 32 |

Selected NMR data of complexes 1-8 is shown in Table 2. Again, complexes 1-4 and 5-8 are clearly different with respect to their chemical shifts of the $\mathrm{CH}_{3}$ moiety atoms. It should be noted that the magnitude of the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ shift is related to the electron-donating capability of the ligands. The results confirm that the better the electron donating ability of the ligand is the larger the high-field shift of the ${ }^{1} \mathrm{H}$ NMR signal of the $\mathrm{Re}-\mathrm{CH}_{3}$ group. The weaker donor capacity of the base ligands in complexes 1-4 are reflected in less pronounced shift differences to non-coordinated MTO.

### 8.2.2 X-ray crystal structure of complex 2

Complex 2 crystallizes in the monoclinic space group $\mathrm{P} 2_{1} / \mathrm{n}$ with $\mathrm{Z}=4$. The molecular solid-state structure is depicted in Figure 1 and the crystallographic data are summarized in the Experimental Section. It is observed that complex 2 displays trans-configuration of the Re-bound $\mathrm{CH}_{3}$ group with respect to the Re-bound Schiff-base oxygen atom. The Re-C bond distance for $\mathbf{2}$ is 2.098(2) $\AA$, which is significantly longer than in free MTO (2.063(2) $\AA$ ). ${ }^{[34]}$ This effect results in a somewhat higher sensitivity of the $\mathrm{Re}-\mathrm{CH}_{3}$ and accordingly, adducts of MTO are generally somewhat less stable than non-coordinated organometallic compound alone. The $\mathrm{Re}=\mathrm{O}$ bond distances of $\mathbf{2}$ are around $1.7 \AA$ and therefore quite similar to the other known MTO adducts in our previous work. ${ }^{[26, ~ 28, ~ 35-36] ~}$

Figure 1. ORTEP style plot of 2 in the solid state. Thermal ellipsoids are drawn at the $50 \%$ probability level. Selected bond lengths ( $\AA$ ) and angels (deg): Re1-O1 1.721(2), Re-O2 1.714(2), Re1-O3 1.742(2), Re-O4 2.231(2), Re1-C1 2.098(2), C2-O4 1.321(3), C8-N1 1.308(3), C9-N1 1.418(3); O1-Re1-O2 118.41(10), O1-Re1-O3 120.35(10), O1-Re1-O4 86.63(9), O1-Re-C1 94.23(10), O2-Re1-O3 119.64(11), O2-Re1-O4 89.12(8), O2-Re1-C1 94.01(10), O3-Re1-O4 81.73(8), O3-Re1-C1 94.37(10), O4-Re1-C1 175.88(9), Re1-O4-C2 129.01(16).

### 8.2.3 Catalytic application

Cis-cycloctene epoxidation catalyzed by $\mathbf{1}$ as model catalyst was examined in different ionic liquids and with different oxidants. The results are given in Figure 2. The details concerning the catalytic reaction are given in the experiment part. A catalyst: oxidant: substrate ratio of 1:200:100 was used in all experiments. Epoxidation of cis-cyclooctene was found to be strongly solvent dependent. When using $[\mathrm{Emim}] \mathrm{BF}_{4}$ (1-ethyl-3-methylimidazolium tetrafluoroborate) and $[B \mathrm{Bmim}] \mathrm{NTf}_{2}$ (1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide) as solvents for epoxidation of cis-cyclooctene, the yield was low (<20 \%). While higher yields (79 \%) were obtained after 24 h in $\left[\mathrm{Bmim}^{2}\right] \mathrm{PF}_{6}$ (1-butyl-3-methylimidazolium hexafluorophosphate) with UHP (urea hydrogen peroxide) as oxidant. For comparison, $\mathrm{H}_{2} \mathrm{O}_{2}$ was also used as oxidant under the same conditions. The catalytic activity is significantly lower with the latter oxidant and diol is formed as by-product. Based on this result, UHP appears to be superior to $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidizing agent.

A blank experiment without oxidant was carried out under the same conditions and no significant oxidation was observed within 24 h , indicating that the oxygen source in the oxidation reaction is not air. It is noteworthy that the advantageous properties of the Schiff-base MTO complexes-UHP oxidation system and the ionic liquid [Bmim] $\mathrm{PF}_{6}$ have to be combined to achieve good conditions for catalytic oxidations. Remaining reactants and products are both easily removed from the reaction mixture via extraction with $n$-hexane,

## Chapter 8

which is immiscible with the ionic liquids used in this work. This method of removing reactants and products is also advantageous because the Schiff base MTO complexes, the peroxorhenium species, and the urea byproduct are insoluble in $n$-hexane.

Figure 2. Epoxidation of cis-cyclooctene with different oxidants in different ionic liquids. 1: $[\mathrm{Emim}] \mathrm{BF}_{4} / \mathrm{UHP}, 2:[\mathrm{Bmim}] \mathrm{NTf}_{2} / \mathrm{UHP}, 3:[\mathrm{Emi}] \mathrm{SE} / \mathrm{UHP}, 4:[\mathrm{Bmim}] \mathrm{PF}_{6} / \mathrm{UHP}, 5:[\mathrm{Bmim}] \mathrm{PF}_{6} / \mathrm{H}_{2} \mathrm{O}_{2}$.

Complexes 1-8 were also examined as catalysts for the epoxidation of cis-cyclooctene using UHP as oxidant in $[\mathrm{Bmim}] \mathrm{PF}_{6}$ at room temperature (Table 3 and Figure 3). Complexes 2 and 4, which have electron donating Schiff base ligands, show the highest activity and conversion of cyclooctene with almost $100 \%$ after 2 h . Complex $\mathbf{3}$ is less catalytic active ( $59 \%$ after 4 h and $70 \%$ after 24 h ). Complex 1 also leads to a good activity and conversion ( $63 \%$ after 6 h and $81 \%$ after 24 h). However it can be seen that 5-8 only show very low catalytic activity achieving yields (< $20 \%$ ) (Entries 6-9) compared with 1-4 (> $60 \%$ ) (Entries 2-5). The comparatively low conversion can be explained by the fact that the coordination of di-nitrogen Schiff bases increases the electron density of Re centre, leading to it being less prone to nucleophilic attack by an olefin. The steric hindrance of the coordinated di-nitrogen Schiff bases additionally hampers the approach of the olefin to the Re atom and appears to be another reason for a slower reaction. ${ }^{[33]}$ It is noteworthy that no diol is detected during the course of the measurements (Table 3). Additionally, figure 3 shows that all catalytic reactions follow first order kinetics. The reaction conversion increases steadily for the first four hours and then slows down.

## Chapter 8

${ }^{\mathrm{a}}$ Reaction condition: cis-cyclooctene ( 2 mmol ), catalyst ( $1 \mathrm{~mol} \%$ ), UHP ( 4 mmol ), $[\mathrm{Bmim}] \mathrm{PF}_{6}(1 \mathrm{~mL})$ at room temperature;
${ }^{\mathrm{b}}$ The conversion and selectivity is calculated by GC analysis.

Figure 3. Time dependent yield of cis-cyclooctene epoxide in the presence of complexes 1-8 as catalysts ( $1 \mathrm{~mol} \%$ ) in ionic liquid $[\mathrm{Bmim}] \mathrm{PF}_{6}$ at room temperature.

Recovery of the $[\mathrm{Bmim}] \mathrm{PF}_{6} / \mathrm{MTO}, \mathbf{2}$ or $\mathbf{4}$ mixture for the oxidation of cyclooctene was also investigated. A problem of this system is that the use of UHP as oxidant results in an accumulation of urea as the reaction medium which is not eliminated in the extraction. Two possible means of removing urea are possible and were applied. The first method is that washing the system with water and then filtration. [Bmim] $\mathrm{PF}_{6}$ is not soluble in water. The IL phase can be dried under vacuum. The new UHP and cyclooctene were added into the IL phase for the next catalytic cycles. The yield of cyclooctene oxide is $30 \%$ for MTO, $7 \%$ for complex 2 and $21 \%$ for complex 4 in the second recycle. It is obvious that washing with water would likely be very effective in removing the urea but would be likely to also remove catalyst. The other method is that dissolving ionic liquid in dichloromethane to precipitate of dissolved urea can be removed subsequently by filtration. Dichloromethane is then removed
under reduced pressure. After the new addition of UHP and cis-cyclooctene further catalytic cycles were attempted. The yield of cyclooctene oxide is $14 \%$ for MTO, $11 \%$ for complex 2 and $3 \%$ for complex 4 using this method in the second recycle. The deactivation was probably due to leaching of the catalyst. This phenomenon is in agreement with previous investigation employing methyltrioxorhenium as an olefin epxodation catalyst in an IL/UHP similar system. ${ }^{[37-38]}$

### 8.3 Conclusion

Eight base adducts of MTO were prepared and characterized. They display good stability in air at room temperature.The complexes were applied as catalysts for the epoxidation of cyclooctene in $\left[\mathrm{Bmim}^{\mathrm{Bm}} \mathrm{BF}_{6}\right.$ with UHP as oxidant at room temperature. The results show that the ( N -salicylidene) aniline derived Schiff base complexes of MTO exhibit higher catalytic activity and selectivity than di-nitrogen Schiff bases complexes of MTO. It is noteworthy that the oxidation reaction yields only the epoxide and not by-product diol. This system provides an environmentally benign way for olefin epoxidation.

### 8.4 Experimental section

### 8.4.1 General

All reactions were performed using standard Schlenk techniques under an argon atmosphere. All solvents were collected from solvent drying systems and kept over molecular sieves. NMR spectra were recorded on a ruker Avance DPX 400 and chemical shifts are reported relative to the residual signal of the deuterated solvent. IR spectra were recorded on Varian FTIR-670 spectrometer, using a GladiATR accessory with a diamond ATR element. Elemental analyses were obtained from the microanalytical laboratory in Technische Universität München. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II. All chemicals were purchased from Acros and ABCR and used without further purification. $[\mathrm{Emim}] \mathrm{BF}_{4},[\mathrm{Bmim}] \mathrm{BF}_{4}$, [ Bmim$]_{\mathrm{NTf}_{2}}$, [Emi]SE (1-ethyl-3-methylimidazolium ethyl sulfate) ionic liquids were synthesized according to literature procedures. ${ }^{[39-40]}$

### 8.4.2 Synthetic methods and characterization data

Synthesis of compounds 1-4: MTO ( $0.2 \mathrm{~g}, 0.8 \mathrm{mmol}$ ) is dissolved in diethyl ether ( 10 mL ) and an equally concentrated solution of ligand $(0.8 \mathrm{mmol})$ in diethyl ether $(10 \mathrm{~mL})$ is added to the stirred solution at room temperature. After 30 min the yellow solution is concentrated in an oil pump vacuum to 3 mL , and the yellow or orange precipitate is obtained by filtration, washed with dry $n$-hexane $(3 \times 10 \mathrm{~mL})$ and dried under reduced pressure.

### 8.4.3 Single-crystal X-ray structure determination

The data were collected on an X-ray diffractometer equipped with a CCD detector (Bruker AXS, APEX II, $\kappa$-CCD), a rotating anode (Bruker AXS, FR591) with MoK $\alpha$ radiation ( $\lambda=$ $0.71073 \AA$ ), and a graphite monochromator. The measurement was performed on a single crystal stored under perfluorinated ether and mounted on glass fiber by using the Smart software package. ${ }^{[41]}$ The crystal was frozen under a stream of cold nitrogen (OXFORD

Cryosystems cooling device). A matrix scan was used to determine the initial lattice parameters. Intensities were integrated and the raw data were corrected for Lorentz, polarization, scan speed, background, and, arising from the scaling procedure, for latent decay and absorption effects using SAINT $4.15{ }^{[42]}$ and SADABS. ${ }^{[43]}$ Space group assignment was based upon systematic absences, E statistics, and successful refinement of the structure. The structure was solved by a combination of direct methods and difference Fourier syntheses and were refined against all data using SHELXL-97. ${ }^{[44]}$ Hydrogen atoms were assigned to ideal positions and refined using a riding model with isotropic thermal parameters 1.2 times that of the attached carbon atom ( 1.5 times for methyl hydrogen atoms). If not mentioned otherwise, non-hydrogen atoms were refined with anisotropic displacement parameters. Full-matrix least-squares refinements were carried out by minimizing $\Sigma \mathrm{w}\left(\mathrm{F}_{\mathrm{o}}{ }^{2}-\mathrm{F}_{\mathrm{c}}{ }^{2}\right)^{2}$ with SHELXL-97 ${ }^{[44]}$ weighting scheme. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. ${ }^{[45]}$ Images of the crystal structures were generated by Platon. ${ }^{[46]}$ Further details are summarized in Table 4.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC-924572 (2). Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, CambridgeCB2 1EZ, U.K. (fax, (+44) 1223-336-033; e-mail, deposit@ccdc.cam.ac.uk.

### 8.4.4 Catalytic reactions

To a solution of cis-cyclooctene ( 2 mmol ) and UHP ( 4 mmol ) in IL ( 1 mL ) was added the catalyst ( $1 \mathrm{~mol} \%$ ) at room temperature. After completion, the reaction mixture was extracted with $n$-hexane $(5 \times 3 \mathrm{~mL})$. The organic phase was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Following the evaporation of the solvent, the crude product was analyzed by GC. The conversion and the formation of cyclooctene oxide were calculated from calibration curves ( $r^{2}>0.999$ ) recorded prior to the start of the reaction.

## 9 New ionic liquids with $\left[\mathrm{Ni}^{\mathrm{I}}(\mathrm{CN})_{4}\right]^{2-}$ anion: synthesis, characterization and catalytic performance

### 9.1 Introduction

Ionic liquids (ILs) have attracted much attention as a replacement for classical solvents in many applications due to their remarkable physical and chemical properties. ${ }^{[1]}$ Most ILs are purely organic onium cations and anions such as $\left[\mathrm{PF}_{6}\right]^{-},\left[\mathrm{BF}_{4}\right]^{-},\left[\left(\mathrm{CF}_{3} \mathrm{SO}_{2}\right)_{2} \mathrm{~N}\right]^{-}$and $\left[\mathrm{CF}_{3} \mathrm{SO}_{2}\right]^{-}$, which are regarded as green media for various reactions. ${ }^{[2]}$ However, metal-containing ILs have been recently developed as new materials, which not only provides unique properties of ILs but also has additional advantages such as geometry, magnetism and catalytic properties in comparison with "organo-ILs". ${ }^{[3]}$ Many of metal-containing ILs which prepared so far by mixing chlorine based ILs with metal chlorides in various molar rations are capable of mediating a wide variety of synthetic reactions and exhibit great potential in catalysis. ${ }^{[4]}$ However, the investigation of potential nickel ion-containing ILs in catalysis seems largely neglected. A small number of imidazolium-based Ni ion containing ILs have been described as catalysts for the reactions. For example, Iwasawa found that this kind of ILs $\left[\mathrm{C}_{\mathrm{n}} \mathrm{mim}\right]_{2}\left[\mathrm{NiCl}_{4}\right]$ catalyzed Suzuki cross-doupling reactions with good yield. ${ }^{[5]}$ Kim reported pyridinium base dicationic ionic salts containing $\left[\mathrm{NiCl}_{4}\right]^{2-}$ can be used as catalysts for the hydrolysis of sodium borohydride. ${ }^{[6]}$ These results promote us to investigate new nickel ion containing IL species involved the properties of ILs and potential catalytic feature. Thus, ILs with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion was developed recently by our group.

In this work, we prepared new ILs based on 1-octyl-3-methylimidazolium ( $\left[\mathrm{C}_{8} \mathrm{mim}\right]^{+}$), 1-dodecyl-3-methylimidazolium $\quad\left(\left[\mathrm{C}_{12} \mathrm{mim}\right]^{+}\right)$, tetra-butyl-phophonium $\quad\left(\left[\mathrm{P}_{4,4,4,4}\right]^{+}\right)$, tributyl-(tetradecyl)-phosphonium $\quad\left(\left[\mathrm{P}_{4,4,4,14}\right]^{+}\right), \quad 1$-octyl-pyridinium $\quad\left[\mathrm{C}_{8} \mathrm{Py}\right]^{+}$and 1-dodecyl-pyridinium $\left[\mathrm{C}_{12} \mathrm{Py}\right]^{+}$with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$. These ILs have high thermal stability and are used as catalysts for epoxidation of olefins.

### 9.2 Results and discussion

### 9.2.1 Synthesis of ILs with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion

A series of ILs with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion was prepared by mixture of cation halide $\left(\left[\mathrm{C}_{8} \mathrm{mim}\right] \mathrm{Br}\right.$, $\left[\mathrm{C}_{12} \mathrm{mim}\right] \mathrm{Br}, \quad\left[\mathrm{P}_{4,4,4,4}\right] \mathrm{Br}, \quad\left[\mathrm{P}_{4,4,4,14}\right] \mathrm{Cl}, \quad\left[\mathrm{C}_{8} \mathrm{Py}\right] \mathrm{Br} \quad$ and $\left.\quad\left[\mathrm{C}_{12} \mathrm{Py}\right] \mathrm{Br}\right)$ and dipotassium tetracyanonickelate in water (Scheme 1). The precipitation was formed immediately. After filtration, the product was washed with water and methanol for three times. The solvent was removed under vacuum. All ILs have high solubility in polar organic solvents such as $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, $\mathrm{CH}_{3} \mathrm{CN}$, common alcohols, but low solubility in $n$-hexane.

### 9.2.2 Characterization of ILs with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion

Thermogravimetric analysis (TGA), differential scanning calorimetry (DSC) and IR spectroscopy data of ILs with $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ are given in Table 1. TGA indicates that all ILs show negligible volatility and high thermal stability with a decomposition temperature more than $270{ }^{\circ} \mathrm{C}$. $\left[\mathrm{C}_{8} \mathrm{mim}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right](\mathbf{1}),\left[\mathrm{P}_{4,4,4,14}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ (4) and $\left[\mathrm{C}_{8} \mathrm{Py}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ (5) are liquid at room temperature. The melting points of $\left[\mathrm{C}_{12} \mathrm{mim}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right](\mathbf{2}),\left[\mathrm{P}_{4,4,4,4}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]\right.$ (3) and $\left[\mathrm{C}_{12} \mathrm{Py}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right](6)$ are $71^{\circ} \mathrm{C}, 141{ }^{\circ} \mathrm{C}$ and $81{ }^{\circ} \mathrm{C}$, respectively. In addition, IR spectroscopy was used to identify the CN group. The CN stretching vibration of ILs lies between 2106-2114 $\mathrm{cm}^{-1}$, which has significant shifted compared to the vibration ( $2119 \mathrm{~cm}^{-1}$ ) of starting material $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ alone.

Table 1. Melting points $\left(T_{m}\right)$, glass transition points $\left(T_{g}\right)$, decomposition temperatures $\left(T_{d}\right)$ and IR data of ILs.

| Entry | ILs | $T_{m} / T_{g}$ <br> $\left({ }^{\circ} \mathrm{C}\right)$ | $T_{d}$ <br> $\left({ }^{\circ} \mathrm{C}\right)$ | IR (CN) <br> $\left(\mathrm{cm}^{-1}\right)$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\left[\mathrm{C}_{8} \mathrm{mim}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ | -52 | 354 | 2113 |
| 2 | $\left[\mathrm{C}_{12} \mathrm{mim}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ | 71 | 327 | 2114 |

### 9.2.3 Catalytic epoxidation of olefins

The ILs 1-6 were examined as catalysts for epoxidation of cis-cyclooctene with TBHP (tert-butyl hydroperoxide) as oxidant in solvent-free at $70{ }^{\circ} \mathrm{C}$ (Figure 1). Further details of the catalytic reaction are given in the experimental section. Blank reactions showed no significant amounts of epoxide were formed in the absence of catalysts. A catalyst: oxidant: substrate ratio of 5:200:100 was used in all experiments.

Figure 1. Yield of cis-cyclooctene epoxidation after 24 h (gray bars) and after 48 h (black bars) with ILs 1-6 as catalysts and TBHP as oxidant agent at $70^{\circ} \mathrm{C}$.

ILs 1-6 showed similar catalytic activity for epoxidation of cis-cyclooctene, indicating the cation of ILs not involved in the catalysis reaction. IL 1 displayed the best catalytic performance achieving more than $60 \%$ yield after 48 h in all ILs. The final solution exhibited no color and no decomposition of ILs was detected in the whole reactions via ${ }^{1} \mathrm{H}$ NMR confirmation. A further catalytic experiment using 1 -octene as substrate was carried out as well. The results showed that a $77 \%$ yield of epoixde was obtained after 24 h using 2 as catalyst and TBHP as oxidant at $70{ }^{\circ} \mathrm{C}$. It is important to note that all ILs showed high epoxidation selectivity (> $99 \%$ ) and no significant by-product such as diol was found in the whole measurements. Figure 2 shows that the catalytic reaction follows first order kinetics in which the reaction conversion increases steadily for the first 6 h and then slows down.

Figure 2. Kinetics of epoxidation of cis-cyclooctene with $\left[\mathrm{C}_{12} \mathrm{mim}\right]_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$ as catalyst and TBHP as oxidant at $70{ }^{\circ} \mathrm{C}$.

### 9.3 Conclusion

A series of ILs based on different cation of ILs and $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ was synthesized and characterized. The preparation of ILs was simple and convenient. All ILs showed negligible volatility and high thermal stability. It was found that theses ILs can be used as catalysts for the epoxidation of olefins with TBHP as oxidant at $70^{\circ} \mathrm{C}$, as well as displaying good activity and high selectivity for epoxides. The present catalytic procedure provides a cheap, safe, easy to handle and environmentally benign alternative.

### 9.4 Experimental section

### 9.4.1 General

All preparations and manipulation involving air sensitive materials were performed using standard Schlenk techniques under argon atmosphere. Solvents were dried by standard procedures ( $\mathrm{Et}_{2} \mathrm{O}$ over $\mathrm{Na} /$ benzophenone; $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ over $\mathrm{CaH}_{2}$ ), distilled under argon and kept over $4 \AA$ molecular sieves. All chemicals (purchased from Acros Organics or Aldrich) were of analytical grade and used as received. ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra were recorded on a Bruker Avance DPX-400 spectrometer and chemical shifts are reported relative to the residual signal deuterated solvent. IR spectra were recorded on Varian FTIR - 670 spectrometer, using a GladiATR accessory with a diamond ATR element. Thermogravimetry coupled with mass spectroscopy (TG-MS) was conducted utilizing a Netzsch TG209 system; typically about 10 mg of each sample were heated form $25{ }^{\circ} \mathrm{C}$ to $1000{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Differential Scanning Calorimetry (DSC) was performed on a Q2000 series DSC instrument; typically about 2 mg of each sample were heated from $-100{ }^{\circ} \mathrm{C}$ to $150{ }^{\circ} \mathrm{C}$ at $10 \mathrm{~K} \mathrm{~min}^{-1}$. Catalytic runs were monitored by GC methods on a Hewlett-Packard instrument HP 5890 Series II equipped with a FID, a Supelco column Alphadex 120 and a Hewlett-Packard integration unit HP 3396 Series II.

Organic and inorganic starting materials were reagent grade from Acros or Aldrich and used as received. The preparation of 1-methyl-3-octyl-imidazolium $\left[\mathrm{C}_{8} \mathrm{mim}\right] \mathrm{Br}$, 1-methyl-3-dodecyl-imidazolium $\left[\mathrm{C}_{12} \mathrm{mim}\right] \mathrm{Br}$, tetrabutylphosphonium bromide $\left[\mathrm{P}_{4,4,4,4}\right] \mathrm{Br}$, tributyl(tetradecyl)phosphonium chloride $\left[\mathrm{P}_{4,4,4,14}\right] \mathrm{Cl}, 1$-(1-octyl)-pyridine bromide $\left[\mathrm{C}_{8} \mathrm{py}\right] \mathrm{Br}$, 1 -(1-dodecyl)-pyridine bromide $\left[\mathrm{C}_{12} \mathrm{py}\right] \mathrm{Br}$ followed literature procedures. ${ }^{[7]}$

### 9.4.2 Synthetic method and characterization data

[CAT]X ( 2 mmol ) was added to a water $(50 \mathrm{~mL})$ solution of according $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right](0.2496 \mathrm{~g}$,
$1 \mathrm{mmol})$. The resulting mixture was stirred for 2 h . After filtration the volatiles were removed in vacuum. The crude product was washed by methanol and water for three times. The desired product was obtained as yellow or white solid.

### 9.4.3 Catalytic reaction

To a solution of cis-cyclooctene ( 2 mmol ) and TBHP ( 4 mmol ) was added the catalyst ( 5 $\mathrm{mol} \%$ ) at $70^{\circ} \mathrm{C}$. After completion, the reaction mixture was extracted with $n$-hexane ( $5 \times 3$ $\mathrm{mL})$. The organic phase treated with a catalytic amount of $\mathrm{MgSO}_{4}$ and $\mathrm{MnO}_{2}$ to remove water and to destroy the excess of peroxide. The resulting slurry was filtered and the filtrate injected into a GC column. The conversion of cis-cyclooctene and the formation of the according oxidewere calculated from calibration curves $\left(r^{2}>0.999\right)$ recorded prior to the reaction course.

## 10 Summary

### 10.1 Imidazolium perrhenate ionic liquids: synthesis, properties and catalytic applications

A series of imidazolium perrhenate ionic liquids (IPILs) $\left[\mathrm{C}_{\mathrm{n}} \mathrm{mim}\right]\left[\mathrm{ReO}_{4}\right]\left(\mathrm{C}_{\mathrm{n}} \mathrm{mim}=\right.$ 1- $\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}+1}$-3-methylimidazolium; $\left.\mathrm{n}=2(\mathbf{1}), 4(\mathbf{2}), 5(\mathbf{3}), 6(\mathbf{4}), 8(\mathbf{5}), 10(\mathbf{6}), 12(7)\right)$ has been synthesized and characterized (Figure 1). Compounds 1-5 are liquids at room temperature and compounds 6 and 7 show a melting point at 38.3 and $48.3{ }^{\circ} \mathrm{C}$, respectively. The thermogravimetric analysis (TGA) data indicates that all the compounds show negligible volatility and high thermal stability with a decomposition onset temperature near $400^{\circ} \mathrm{C}$.

| $12 ;$ | $\mathbf{7}$ |

Figure 1. Imidazolium perrhenate ionic liquids.
IPILs 2, 5 and $\mathbf{7}$ were found to be very efficient reaction media for the epoxidation of olefins (cyclooctene, 1-octene, styrene) with $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant, thus affording good yields. In all examined epoxidation reaction, $\mathrm{H}_{2} \mathrm{O}_{2}$ is superior to UHP and TBHP. Furthermore, this system can be recycled at least eight times with constant yields of 98-99 \%, which demonstrates the high stability of the IL under oxidative conditions, thus rendering it a good candidate for efficient olefin epoxidation.

Additionally, the IPILs exhibit good catalytic abilities for oxidation of sulfides to sulfones with hydrogen peroxide as oxidant in the normal ionic liquid $[\mathrm{Bmim}]\left[\mathrm{BF}_{4}\right]$ at $60^{\circ} \mathrm{C}$. A series of sulfones was obtained with high yields under mild reaction conditions. Furthermore, the functional groups, such as double bonds, hydroxyl groups and esters are tolerated and no epoxidation and aldehyde formation is observed. This was demonstrated that IPILs could be reused at least ten times without considerable loss of activity. The conversion and yield did not decrease on recycling and the products obtained were the desired sulfones.

For the mechanism, formation of $\mathrm{O}_{3} \mathrm{Re}-\mathrm{O} \cdots \mathrm{H}-\mathrm{O}-\mathrm{OH}$ species between the peroxide with IPILs was detected using IR, Raman and DFT calculations techniques. These hydrogen

## Chapter 10

bridged moieties play a key role in both epoxidation and sulfoxidation reactions. In the IR spectra, the experimentally observed splitting ( $890-920 \mathrm{~cm}^{-1}$ ) of the former asymmetric stretching mode of the pure ionic liquid, which was found at about $900 \mathrm{~cm}^{-1}$, was also reflected in the simulated spectra. In the Raman spectra, the asymmetric stretching mode of the pure ionic liquid at about $916 \mathrm{~cm}^{-1}$, was broadened to $885-930 \mathrm{~cm}^{-1}$. Point group analysis showed that this is consistent with a lowering of the local symmetry of $\left[\mathrm{ReO}_{4}\right]^{-}$from $\mathrm{T}_{d}$ to $\mathrm{C}_{2 v}$. All these changes can be assigned to a distortion of the local symmetry of the anion by weak coordination H-bond, which is supported by DFT calculations as well.

### 10.2 Oxidation of sulfides to sulfoxides in metal-free ionic liquids

In continuation of the studies described above, new ionic liquids utilizing different cations with a new family of $\left[\mathrm{B}\left(\mathrm{Ar}^{\mathrm{F}}\right)_{4}\right]$ species have been synthesized and structurally characterized. The synthesis was optimized and is now simple, and the products can be obtained in high yields. All salts have high thermal stability. It has been shown that the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{3}-3,5-\left(\mathrm{CF}_{3}\right)_{2}\right)_{4}\right]^{-}$ anion salts ( $\mathbf{2 b}, \mathbf{3 b}, \mathbf{5 b}$ and $\mathbf{6 b}$ ) melting points are reduced by $100{ }^{\circ} \mathrm{C}$ compared to the $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$salts, which lead to opportunities to form ILs materials. The melting points of the salts using tetrabutylammonium and 1,1,3,3-tetramethylguanidium as cation are higher than those of any other salts due to the high symmetry structure. Increasing the size of the salts has been identified as a common and potentially general characteristic of low melting points with large cation. The systematic variation of alkyl substituent on the cation led to usefully predictive trends in melting points. It is important to mention that hydrogen-bonding interactions between $[\mathrm{TMG}]^{+}$and $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$has been discovered.

The ionic liquid $\left[\mathrm{P}_{4,4,4,14}\right]\left[\mathrm{B}\left(3,5-\left(\mathrm{CF}_{3}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right)_{4}\right]$ and normal ionic liquid $\left[\mathrm{C}_{4} \mathrm{mim}\right] \mathrm{BF}_{4}$ can be successfully applied for oxidation of sulfides to sulfoxides without catalyst (Scheme 1). The results show that faster oxidation rate of aliphatic sulfides than aromatic sulfidesis due to higher nucleophilicity. Furthermore, these two systems can be recycled for at least four times without loss of activity.

Scheme 1. Oxidation of sulfides to sulfoxides in ILs
The reaction mechanism was examined by IR, Raman and NMR spectroscopy. From these examinations it can be concluded that the crucial step during the oxidation procedure is the
formation of a hydrogen bond between ionic liquid and oxidant.

### 10.3 Oxidation reactions with polyoxomolybdate salts and MTO Schiff base complexes in ionic liquids

### 10.3.1 Oxidation reactions catalyzed by polyoxomolybdate salts in ILs

Ionic compounds containing the polyoxomolybdate anion $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$ and a variety of cations were prepared, characterized and investigated with respect to their activity in the epoxidation of several olefins and oxidation of a series of sulfides (Figure 2). Three of the solid state structures were determined by single-crystal X-ray diffraction, exhibiting H...O bond between cation and anion $\left[\mathrm{Mo}_{6} \mathrm{O}_{19}\right]^{2-}$.

These compounds were applied as catalysts for the epoxidation of olefins with urea hydrogen peroxide (UHP) as oxidant in the ionic liquid $[\mathrm{Bmim}] \mathrm{PF}_{6}$ at $70^{\circ} \mathrm{C}$. The results show that the highest yield was obtained using cyclooctene and cyclohexane as substracts. With regard to some other olefins such as trans- $\beta$-methylstyrene, limonene, cis-stilbene and (+)-camphene, the reactions were rather challenging due to steric hindrance. Moreover, this catalytic procedure was repeated three times with only a minor loss of activity. It was found that the reaction is selective to the desired epoxide in all runs and no diol formation was observed. On the other hand, the oxidation of sulfides to sulfoxides with hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ as oxidant and polyoxomolybdate salts as catalysts in MeOH was also investigated. The polyoxomolybdate catalysts show a good performance for oxidation of sulfides to sulfoxides. This system can be reused five times without any loss of activity.

### 10.3.2 Epoxidation of olefins catalyzed by MTO Schiff base complexes in ILs

A series of different Schiff base methyltrioxorhenium (VII) complexes have been synthesized and investigated with repect to their activity in the epoxidation of several olefins (Figure 3).

Chapter 10

Figure 3.MTO Schiff base complexes

They display good air stability at room temperature. The complexes were applied as catalysts for the epoxidation of cyclooctene in the ionic liquid $[\mathrm{Bmim}] \mathrm{PF}_{6}$ with UHP as oxidant at room temperature. Surprisingly, the MTO complexes are also active when UHP was used as oxidant. It was found that the ( N -salicylidene) aniline derived Schiff base complexes of MTO exhibit higher catalytic activity and selectivity than di-nitrogen Schiff bases complexes of MTO. It is noteworthy that this reaction is carried out in non-aqueous media, thus no diol by-product was found during the measurements.

Figure 11. ${ }^{11} \mathrm{~B}$ NMR of $[\mathrm{Bmim}] \mathrm{BF}_{4}(1)$ and $[\mathrm{Bmim}] \mathrm{BF}_{4}+\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)$ (2) system.

Figure 12. ${ }^{19} \mathrm{~F}$ NMR of $[\mathrm{Bmim}] \mathrm{BF}_{4}(1)$ and $[\mathrm{Bmim}] \mathrm{BF}_{4}+\mathrm{H}_{2} \mathrm{O}_{2}(35 \%)(2)$ system.

## Chapter 11

### 11.3 This section contains supplementary information to chapter 5: ionic liquid with the weakly coordinating anions: synthesis, properties and application

### 11.3.1 Single crystal $X$-Ray structure determination of compounds $\mathbf{4 a}, \mathbf{7 a}, \mathbf{2 b}$ and $\mathbf{5 b}$

## General:

Data were collected on an X-ray single crystal diffractometer equipped with a CCD detector (Bruker APEX II, $\kappa$-CCD), a rotating anode (Bruker AXS, FR591) with $\mathrm{MoK}_{\square}$ radiation ( $\lambda=$ $0.71073 \AA$ ), and a graphite monochromator by using the SMART software package. ${ }^{[1]}$ The measurements were performed on a single crystal coated with perfluorinated ether. The crystal was fixed on the top of a glass fiber and transferred to the diffractometer. The crystal was frozen under a stream of cold nitrogen. A matrix scan was used to determine the initial lattice parameters. Reflections were merged and corrected for Lorenz and polarization effects, scan speed, and background using SAINT. ${ }^{[2]}$ Absorption corrections, including odd and even ordered spherical harmonics were performed using SADABS. ${ }^{[2]}$ Space group assignments were based upon systematic absences, $E$ statistics, and successful refinement of the structures. Structures were solved by direct methods with the aid of successive difference Fourier maps, and were refined against all data using WinGX ${ }^{[7]}$ based on SIR-92. ${ }^{[3]}$ If not mentioned otherwise, non-hydrogen atoms were refined with anisotropic displacement parameters. Methyl hydrogen atoms were refined as part of rigid rotating groups, with C $-\mathrm{H}=0.98 \AA$ and $U_{\text {iso(H) }}=1.5 U_{\text {eq(C) }}$. Other H atoms were placed in calculated positions and refined using a riding model, with methylene and aromatic $\mathrm{C}-\mathrm{H}$ distances of 0.99 and $0.95 \AA$, respectively, and $\mathrm{U}_{\mathrm{iso}(\mathrm{H})}=1.2 \cdot \mathrm{U}_{\mathrm{eq}(\mathrm{C})}$. Full-matrix least-squares refinements were carried out by minimizing $\Sigma w\left(\mathrm{~F}_{\mathrm{o}}{ }^{2}-\mathrm{F}_{\mathrm{c}}{ }^{2}\right)^{2}$ with SHELXL- $97^{[5]}$ weighting scheme. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. ${ }^{[4]}$ Images of the crystal structures were generated by PLATON. ${ }^{[6]}$ CCDC 956711 (4a), CCDC 956713 (7a), CCDC 956714 (2b) and CCDC 956712 (5b) contains the supplementary crystallographic data for this compound. This data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif viahttps://www.ccdc.cam.ac.uk/services/structure_deposit/

## Chapter 11

## Special:

4a: Twin refinement (twin operation: inversion)

7a: Hydrogen atoms could be located in the difference Fourier maps and were allowed to refine freely.

2b: $\quad$ Four $\mathrm{CF}_{3}$-Groups are disordered over two positions.
The butyl-Group of the cation is disordered over two positions.
Diffractometer: Kappa APEX II (BruKER AXS); sealed tube

5b: $\quad$ Three $\mathrm{CF}_{3}$-Groups are disordered over two positions.

### 11.4.2 Bond distances and angles of compounds 1,3 and 4

## Bond distances and angles of 1

$\mathrm{C}_{32} \mathrm{H}_{72} \mathrm{PMo}_{6} \mathrm{O}_{19}$ (1):a clear pale yellow fragment-like specimen of $\mathrm{C}_{32} \mathrm{H}_{72} \mathrm{Mo}_{6} \mathrm{O}_{19} \mathrm{P}_{2}$, approximate dimensions $0.252 \mathrm{~mm} \times 0.260 \mathrm{~mm} \times 0.469 \mathrm{~mm}$, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured.A total of 2592 frames were collected. The total exposure time was 7.20 h . The frames were integrated with the

## Chapter 11

Bruker SAINT software package using a narrow-frame algorithm. The integration of the data using a monoclinic unit cell yielded a total of 42081 reflections to a maximum $\theta$ angle of $25.35^{\circ}(0.83 \AA$ resolution $)$. The final cell constants of $\mathrm{a}=16.0547(3) \AA, \mathrm{b}=16.0680(3) \AA, \mathrm{c}=$ $19.7281(4) \AA, \beta=106.2476(7)^{\circ}$, volume $=4885.94(16) \AA^{3}$, are based upon the refinement of the XYZ-centroids of 216 reflections above $20 \sigma(\mathrm{I})$ with $3.605^{\circ}<2 \theta<66.77^{\circ}$. Data were corrected for absorption effects using the multi-scan method (SADABS). The ratio of minimum to maximum apparent transmission was 0.909 . Bond distances and angles of $\mathbf{1}$ are shown in Table S2 and Table S3.

Table 2. Bond distances ( $\AA$ ) in compound 1.

## Chapter 11

## Bond distances and angles of 3

$\mathrm{C}_{16} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{Mo}_{6} \mathrm{O}_{19}(\mathbf{3})$ : a clear light yellow fragment-like specimen of $\mathrm{Mo}_{6} \mathrm{O}_{19}, 2\left(\mathrm{C}_{8} \mathrm{H}_{15} \mathrm{~N}_{2}\right)$, approximate dimensions $0.104 \times 0.196 \times 0.220 \mathrm{~mm}$, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured. A total of 3967 frames were collected. The total exposure time was 5.51 h . The frames were integrated with the Bruker Saint software package using a narrow-frame algorithm. The integration of the data using a monoclinic unit cell yielded a total of 48484 reflections to a maximum $\theta$ angle of $25.62^{\circ}$ ( $0.82 \AA$ resolution), of which 2838 were independent (average redundancy 17.084, completeness $=98.2 \%, \mathrm{R}_{\text {int }}=$ $\left.4.83 \%, \mathrm{R}_{\mathrm{sig}}=1.79 \%\right)$ and $2586(91.12 \%)$ were greater than $2 \sigma(\mathrm{~F} 2)$. The final cell constants of $\mathrm{a}=8.5458(16) \AA, \mathrm{b}=17.085(3) \AA, \mathrm{c}=11.075(2) \AA, \beta=108.937(8)^{\circ}$, volume $=1529.5(5)$ $\AA^{3}$, are based upon the refinement of the XYZ-centroids of 61 reflections above $20 \sigma(\mathrm{I})$ with $4.568^{\circ}<2 \theta<56.01^{\circ}$. Data were corrected for absorption effects using the multi-scan method (SADABS). The ratio of minimum to maximum apparent transmission was 0.894 . Bond distances and angles of $\mathbf{3}$ are shown in Table S4 and Table S5.

## Bond distances and angles of 4

$\mathrm{C}_{18} \mathrm{H}_{34} \mathrm{~N}_{4} \mathrm{Mo}_{6} \mathrm{O}_{19}$ (4): a clear light yellow fragment-like specimen of $2\left(\mathrm{C}_{9} \mathrm{H}_{17} \mathrm{~N}_{2}\right), \mathrm{Mo}_{6} \mathrm{O}_{19}$, approximate dimensions $0.240 \mathrm{~mm} \times 0.410 \mathrm{~mm} \times 0.460 \mathrm{~mm}$, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured. A total of 3797 frames were collected. The total exposure time was 5.28 h . The frames were integrated with the Bruker SAINT software package using a narrow-frame algorithm. The integration of the data using a monoclinic unit cell yielded a total of 40353 reflections to a maximum $\theta$ angle of $25.47^{\circ}$ ( $0.83 \AA$ resolution), of which 2989 were independent (average redundancy 13.501, completeness $\left.=99.9 \%, \mathrm{R}_{\text {int }}=8.15 \%, \mathrm{R}_{\text {sig }}=2.24 \%\right)$ and $2902(97.09 \%)$ were greater than

## Chapter 11

$2 \sigma(\mathrm{~F} 2)$. The final cell constants of $\mathrm{a}=11.0074(2) \AA, \mathrm{b}=10.7827(2) \AA, \mathrm{c}=13.5900(3) \AA, \beta=$ $91.0450(10)^{\circ}$, volume $=1612.72(5) \AA^{3}$, are based upon the refinement of the XYZ-centroids of 179 reflections above $20 \sigma(\mathrm{I})$ with $3.027^{\circ}<2 \theta<65.42^{\circ}$. Data were corrected for absorption effects using the multi-scan method (SADABS). The ratio of minimum to maximum apparent transmission was 0.788 . The calculated minimum and maximum transmission coefficients (based on crystal size) are 0.4091 and 0.5983 . Bond distances and angles of $\mathbf{4}$ are shown in Table S6 and Table S7.

## 12 Permissions for reuse of publications

### 12.1 RSC Journals

Dear Bo
The Royal Society of Chemistry (RSC) hereby grants permission for the use of yourpaper(s) specified below in the printed and microfilm version of your thesis. Youmay also make available the PDF version of your paper(s) that the RSC sent to thecorresponding author(s) of your paper(s) upon publication of the paper(s) in thefollowing ways: in your thesis via any website that your university may have for thedeposition of theses, via your university's Intranet or via your own personalwebsite. We are however unable to grant you permission to include the PDF versionof the paper(s) on its own in your institutional repository. The Royal Society ofChemistry is a signatory to the STM Guidelines on Permissions (available onrequest).

Please note that if the material specified below or any part of it appears withcredit or acknowledgement to a third party then you must also secure permission fromthat third party before reproducing that material.

Please ensure that the thesis states the following:
Reproduced by permission of The Royal Society of Chemistryand include a link to the paper on the Royal Society of Chemistry's website.

Please ensure that your co-authors are aware that you are including the paper inyour thesis.

## Regards

Subject: reuse of publications for cumulative dissertation
Dear Ladies and Gentlemen:
I would like to request your permission, so I can reuse the following articles in mythesis which I have authored:
B. Zhang, M.D.Zhou, M. Cokoja, J.Mink, S.L. Zang, and F. E. Kühn, RSC advances 2012, 2, 8416-8420.

My thesis will not be published online. However, a printed version will be made for University purposes.

Thank you very much.
Best regards,
Bo Zhang

Terms and Conditions

## TERMS AND CONDITIONS

This copyrighted material is owned by or exclusively licensed to John Wiley \& Sons, Inc. or one of its group companies (each a "Wiley Company") or a society for whom a Wiley Company has exclusive publishing rights in relation to a particular journal (collectively "WILEY"). By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the billing and payment terms and conditions established by the Copyright Clearance Center Inc., ("CCC's Billing and Payment terms and conditions"), at the time that you opened your RightsLink account (these are available at any time at http://myaccount.copyright.com).

## Terms and Conditions

1. The materials you have requested permission to reproduce (the "Materials") are protected by copyright.
2. You are hereby granted a personal, non-exclusive, non-sublicensable, non-transferable,
worldwide, limited license to reproduce the Materials for the purpose specified in the licensing process. This license is for a one-time use only with a maximum distribution equal to the number that you identified in the licensing process. Any form of republication granted by this license must be completed within two years of the date of the grant of this license (although copies prepared before may be distributed thereafter). The Materials shall not be used in any other manner or for any other purpose. Permission is granted subject to an appropriate acknowledgement given to the author, title of the material/book/journal and the publisher. You shall also duplicate the copyright notice that appears in the Wiley publication in your use of the Material. Permission is also granted on the understanding that nowhere in the text is a previously published source acknowledged for all or part of this Material. Any third party material is expressly excluded from this permission.
3. With respect to the Materials, all rights are reserved. Except as expressly granted by the terms of the license, no part of the Materials may be copied, modified, adapted (except for minor reformatting required by the new Publication), translated, reproduced, transferred or distributed, in any form or by any means, and no derivative works may be made based on the Materials without the prior permission of the respective copyright owner. You may not alter, remove or suppress in any manner any copyright, trademark or other notices displayed by the Materials. You may not license, rent, sell, loan, lease, pledge, offer as security, transfer or assign the Materials, or any of the rights granted to you hereunder to any other person.
4. The Materials and all of the intellectual property rights therein shall at all times remain the exclusive property of John Wiley \& Sons Inc or one of its related companies (WILEY) or their respective licensors, and your interest therein is only that of having possession of and the right to reproduce the Materials pursuant to Section 2 herein during the continuance of this Agreement. You agree that you own no right, title or interest in or to the Materials or any of the intellectual property rights therein. You shall have no rights hereunder other than the license as provided for above in Section 2. No right, license or interest to any trademark, trade name, service mark or other branding ("Marks") of WILEY or its licensors is granted hereunder, and you agree that you shall not assert any such right, license or interest with respect thereto.

## 5. NEITHER WILEY NOR ITS LICENSORS MAKES ANY WARRANTY OR REPRESENTATION OF ANY KIND TO YOU OR ANY THIRD PARTY, EXPRESS, IMPLIED OR STATUTORY, WITH RESPECT TO THE MATERIALS OR THE ACCURACY OF ANY INFORMATION CONTAINED IN THE MATERIALS, INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, ACCURACY, SATISFACTORY QUALITY, FITNESS FOR A PARTICULAR PURPOSE, USABILITY, INTEGRATION OR NON-INFRINGEMENT AND ALL SUCH WARRANTIES ARE HEREBY EXCLUDED BY WILEY AND ITS LICENSORS AND WAIVED BY YOU.

6. WILEY shall have the right to terminate this Agreement immediately upon breach of this Agreement by you.
7. You shall indemnify, defend and hold harmless WILEY, its Licensors and their respective directors, officers, agents and employees, from and against any actual or threatened claims, demands, causes of action or proceedings arising from any breach of this Agreement by you.

#### Abstract

8. IN NO EVENT SHALL WILEY OR ITS LICENSORS BE LIABLE TO YOU OR ANY OTHER PARTY OR ANY OTHER PERSON OR ENTITY FOR ANY SPECIAL, CONSEQUENTIAL, INCIDENTAL, INDIRECT, EXEMPLARY OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING OUT OF OR IN CONNECTION WITH THE DOWNLOADING, PROVISIONING, VIEWING OR USE OF THE MATERIALS REGARDLESS OF THE FORM OF ACTION, WHETHER FOR BREACH OF CONTRACT, BREACH OF WARRANTY, TORT, NEGLIGENCE, INFRINGEMENT OR OTHERWISE (INCLUDING, WITHOUT LIMITATION, DAMAGES BASED ON LOSS OF PROFITS, DATA, FILES, USE, BUSINESS OPPORTUNITY OR CLAIMS OF THIRD PARTIES), AND WHETHER OR NOT THE PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. THIS LIMITATION SHALL APPLY NOTWITHSTANDING ANY FAILURE OF ESSENTIAL PURPOSE OF ANY LIMITED REMEDY PROVIDED HEREIN.

9. Should any provision of this Agreement be held by a court of competent jurisdiction to be illegal, invalid, or unenforceable, that provision shall be deemed amended to achieve as nearly as possible the same economic effect as the original provision, and the legality, validity and enforceability of the remaining provisions of this Agreement shall not be affected or impaired thereby.
10. The failure of either party to enforce any term or condition of this Agreement shall not constitute a waiver of either party's right to enforce each and every term and condition of this Agreement. No breach under this agreement shall be deemed waived or excused by either party unless such waiver or consent is in writing signed by the party granting such waiver or consent. The waiver by or consent of a party to a breach of any provision of this Agreement shall not operate or be construed as a waiver of or consent to any other or subsequent breach by such other party.
11. This Agreement may not be assigned (including by operation of law or otherwise) by you without WILEY's prior written consent.
12. Any fee required for this permission shall be non-refundable after thirty (30) days from receipt
13. These terms and conditions together with CCC's Billing and Payment terms and conditions (which are incorporated herein) form the entire agreement between you and WILEY concerning this licensing transaction and (in the absence of fraud) supersedes all prior agreements and representations of the parties, oral or written. This Agreement may not be amended except in writing signed by both parties. This Agreement shall be binding upon and inure to the benefit of the parties' successors, legal representatives, and authorized assigns.
14. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall prevail.
15. WILEY expressly reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
16. This Agreement will be void if the Type of Use, Format, Circulation, or Requestor Type
was misrepresented during the licensing process.
17. This Agreement shall be governed by and construed in accordance with the laws of the State of New York, USA, without regards to such state's conflict of law rules. Any legal action, suit or proceeding arising out of or relating to these Terms and Conditions or the breach thereof shall be instituted in a court of competent jurisdiction in New York County in the State of New York in the United States of America and each party hereby consents and submits to the personal jurisdiction of such court, waives any objection to venue in such court and consents to service of process by registered or certified mail, return receipt requested, at the last known address of such party.

## Wiley Open Access Terms and Conditions

Wiley publishes Open Access articles in both its Wiley Open Access Journals program [http://www.wileyopenaccess.com/view/index.html] and as Online Open articles in its subscription journals. The majority of Wiley Open Access Journals have adopted the Creative Commons Attribution License (CC BY) which permits the unrestricted use, distribution, reproduction, adaptation and commercial exploitation of the article in any medium. No permission is required to use the article in this way provided that the article is properly cited and other license terms are observed. A small number of Wiley Open Access journals have retained the Creative Commons Attribution Non Commercial License (CC BY-NC), which permits use, distribution and reproduction in any medium, provided the original work is properly cited and is not used for commercial purposes.

Online Open articles - Authors selecting Online Open are, unless particular exceptions apply, offered a choice of Creative Commons licenses. They may therefore select from the CC BY, the CC BY-NC and the Attribution-NoDerivatives (CC BY-NC-ND). The CC BY-NC-ND is more restrictive than the CC BY-NC as it does not permit adaptations or modifications without rights holder consent.

Wiley Open Access articles are protected by copyright and are posted to repositories and websites in accordance with the terms of the applicable Creative Commons license referenced on the article. At the time of deposit, Wiley Open Access articles include all changes made during peer review, copyediting, and publishing. Repositories and websites that host the article are responsible for incorporating any publisher-supplied amendments or retractions issued subsequently.
Wiley Open Access articles are also available without charge on Wiley's publishing platform, Wiley Online Library or any successor sites.

Conditions applicable to all Wiley Open Access articles:

- The authors' moral rights must not be compromised. These rights include the right of "paternity" (also known as "attribution" - the right for the author to be identified as such) and "integrity" (the right for the author not to have the work altered in such a way that the author's reputation or integrity may be damaged).
- Where content in the article is identified as belonging to a third party, it is the obligation of the user to ensure that any reuse complies with the copyright policies of the owner of that content.
- If article content is copied, downloaded or otherwise reused for research and other purposes as permitted, a link to the appropriate bibliographic citation (authors, journal, article title, volume, issue, page numbers, DOI and the link to the definitive published version on Wiley Online

## Chapter 12

Library) should be maintained. Copyright notices and disclaimers must not be deleted.

- Creative Commons licenses are copyright licenses and do not confer any other rights, including but not limited to trademark or patent rights.
- Any translations, for which a prior translation agreement with Wiley has not been agreed, must prominently display the statement: "This is an unofficial translation of an article that appeared in a Wiley publication. The publisher has not endorsed this translation."

## Conditions applicable to non-commercial licenses (CC BY-NC and CC BY-NC-ND)

For non-commercial and non-promotional purposes individual non-commercial users may access, download, copy, display and redistribute to colleagues Wiley Open Access articles. In addition, articles adopting the CC BY-NC may be adapted, translated, and text- and data-mined subject to the conditions above.

## Use by commercial 'for-profit" organizations

Use of non-commercial Wiley Open Access articles for commercial, promotional, or marketing purposes requires further explicit permission from Wiley and will be subject to a fee. Commercial purposes include:

- Copying or downloading of articles, or linking to such articles for further redistribution, sale or licensing;
- Copying, downloading or posting by a site or service that incorporates advertising with such content;
- The inclusion or incorporation of article content in other works or services (other than normal quotations with an appropriate citation) that is then available for sale or licensing, for a fee (for example, a compilation produced for marketing purposes, inclusion in a sales pack)
- Use of article content (other than normal quotations with appropriate citation) by for-profit organizations for promotional purposes
- Linking to article content in e-mails redistributed for promotional, marketing or educational purposes;
- Use for the purposes of monetary reward by means of sale, resale, license, loan, transfer or other form of commercial exploitation such as marketing products
- Print reprints of Wiley Open Access articles can be purchased from: corporatesales@wiley.com

The modification or adaptation for any purpose of an article referencing the CC BY-NC-ND License requires consent which can be requested from RightsLink@wiley.com.

Other Terms and Conditions:

> BY CLICKING ON THE "I AGREE..." BOX, YOU ACKNOWLEDGE THAT YOU HAVE READ AND FULLY UNDERSTAND EACH OF THE SECTIONS OF AND PROVISIONS SET FORTH IN THIS AGREEMENT AND THAT YOU ARE IN AGREEMENT WITH AND ARE WILLING TO ACCEPT ALL OF YOUR OBLIGATIONS AS SET FORTH IN THIS AGREEMENT.
v1.8
If you would like to pay for this license now, please remit this license along with your payment made payable to "COPYRIGHTCLEARANCECENTER" otherwise you will be invoiced within 48 hours of the license date. Payment should be in the form of a check or money order referencing your account number and this invoice number RLNK501131550.
Once you receive your invoice for this order, you may pay your invoice by credit card. Please follow instructions provided at that time.

Make Payment To:
Copyright Clearance Center

Terms and Conditions

## INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

## GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.
3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:
"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."
4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.
5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions,
deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com)
6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.
7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.
9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.
10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.
11. No Transfer of License: This license is personal to you and may not be sublicensed, assigned, or transferred by you to any other person without publisher's written permission.
12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).
13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.
14. Revocation: Elsevier or CopyrightClearanceCenter may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full
refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or CopyrightClearanceCenter be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or CopyrightClearanceCenter for denied permissions.

## LIMITED LICENSE

The following terms and conditions apply only to specific license types:
15. Translation: This permission is granted for non-exclusive world English rights only unless your license was granted for translation rights. If you licensed translation rights you may only translate this content into the languages you requested. A professional translator must perform all translations and reproduce the content word for word preserving the integrity of the article. If this license is to re-use 1 or 2 figures then permission is granted for non-exclusive world rights in all languages.
16. Website: The following terms and conditions apply to electronic reserve and author websites:
Electronic reserve: If licensed material is to be posted to website, the web site is to be password-protected and made available only to bona fide students registered on a relevant course if:
This license was made in connection with a course,
This permission is granted for 1 year only. You may obtain a license for future website posting,
All content posted to the web site must maintain the copyright information line on the bottom of each image,
A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx or the Elsevier homepage for books at http://www.elsevier.com , and
Central Storage: This license does not include permission for a scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.
17. Author website for journals with the following additional clauses:

All content posted to the web site must maintain the copyright information line on the bottom of each image, and the permission granted is limited to the personal version of your paper. You are not allowed to download and post the published electronic version of your article (whether PDF or HTML, proof or final version), nor may you scan the printed edition to create an electronic version. A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx. As part of our normal production process, you will receive an e-mail notice when your article appears on Elsevier's online service ScienceDirect (www.sciencedirect.com). That e-mail will include the article's Digital Object Identifier (DOI). This number provides the electronic link to the published article and should be included in the posting of your personal version. We ask that you wait until you receive this e-mail and have the DOI to do any posting.

Central Storage: This license does not include permission for a scanned version of the
material to be stored in a central repository such as that provided by Heron/XanEdu.
18. Author website for books with the following additional clauses:

Authors are permitted to place a brief summary of their work online only.
A hyper-text must be included to the Elsevier homepage at http://www.elsevier.com . All content posted to the web site must maintain the copyright information line on the bottom of each image. You are not allowed to download and post the published electronic version of your chapter, nor may you scan the printed edition to create an electronic version.

Central Storage: This license does not include permission for a scanned version of the material to be stored in a central repository such as that provided by Heron/XanEdu.
19. Website (regular and for author): A hyper-text must be included to the Homepage of the journal from which you are licensing at http://www.sciencedirect.com/science/journal/xxxxx. or for books to the Elsevier homepage at http://www.elsevier.com
20. Thesis/Dissertation: If your license is for use in a thesis/dissertation your thesis may be submitted to your institution in either print or electronic form. Should your thesis be published commercially, please reapply for permission. These requirements include permission for the Library and Archives of Canada to supply single copies, on demand, of the complete thesis and include permission for UMI to supply single copies, on demand, of the complete thesis. Should your thesis be published commercially, please reapply for permission.

## 21. Other Conditions:

v1.6
If you would like to pay for this license now, please remit this license along with your payment made payable to "COPYRIGHTCLEARANCECENTER" otherwise you will be invoiced within 48 hours of the license date. Payment should be in the form of a check or money order referencing your account number and this invoice number RLNK501131555.
Once you receive your invoice for this order, you may pay your invoice by credit card. Please follow instructions provided at that time.

## Make Payment To:

Copyright Clearance Center
Dept 001
P.O. Box 843006

Boston, MA 02284-3006
For suggestions or comments regarding this order, contact RightsLink Customer Support: customercare@copyright.com or +1-877-622-5543 (toll free in the US) or +1 -978-646-2777.

## Gratis licenses (referencing \$0 in the Total field) are free. Please retain this printable license for your reference. No payment is required.

This is a License Agreement between Bo Zhang ("You") and Elsevier ("Elsevier") provided by CopyrightClearanceCenter ("CCC"). The license consists of your order details, the terms and conditions provided by Elsevier, and the payment terms and conditions.

## All payments must be made in full to CCC. For payment instructions, please see information listed at the bottom of this form.

Terms and Conditions

## INTRODUCTION

1. The publisher for this copyrighted material is Elsevier. By clicking "accept" in connection with completing this licensing transaction, you agree that the following terms and conditions apply to this transaction (along with the Billing and Payment terms and conditions established by Copyright Clearance Center, Inc. ("CCC"), at the time that you opened your Rightslink account and that are available at any time at http://myaccount.copyright.com).

## GENERAL TERMS

2. Elsevier hereby grants you permission to reproduce the aforementioned material subject to the terms and conditions indicated.
3. Acknowledgement: If any part of the material to be used (for example, figures) has appeared in our publication with credit or acknowledgement to another source, permission

## Chapter 12

must also be sought from that source. If such permission is not obtained then that material may not be included in your publication/copies. Suitable acknowledgement to the source must be made, either as a footnote or in a reference list at the end of your publication, as follows:
"Reprinted from Publication title, Vol /edition number, Author(s), Title of article / title of chapter, Pages No., Copyright (Year), with permission from Elsevier [OR APPLICABLE SOCIETY COPYRIGHT OWNER]." Also Lancet special credit - "Reprinted from The Lancet, Vol. number, Author(s), Title of article, Pages No., Copyright (Year), with permission from Elsevier."
4. Reproduction of this material is confined to the purpose and/or media for which permission is hereby given.
5. Altering/Modifying Material: Not Permitted. However figures and illustrations may be altered/adapted minimally to serve your work. Any other abbreviations, additions, deletions and/or any other alterations shall be made only with prior written authorization of Elsevier Ltd. (Please contact Elsevier at permissions@elsevier.com)
6. If the permission fee for the requested use of our material is waived in this instance, please be advised that your future requests for Elsevier materials may attract a fee.
7. Reservation of Rights: Publisher reserves all rights not specifically granted in the combination of (i) the license details provided by you and accepted in the course of this licensing transaction, (ii) these terms and conditions and (iii) CCC's Billing and Payment terms and conditions.
8. License Contingent Upon Payment: While you may exercise the rights licensed immediately upon issuance of the license at the end of the licensing process for the transaction, provided that you have disclosed complete and accurate details of your proposed use, no license is finally effective unless and until full payment is received from you (either by publisher or by CCC) as provided in CCC's Billing and Payment terms and conditions. If full payment is not received on a timely basis, then any license preliminarily granted shall be deemed automatically revoked and shall be void as if never granted. Further, in the event that you breach any of these terms and conditions or any of CCC's Billing and Payment terms and conditions, the license is automatically revoked and shall be void as if never granted. Use of materials as described in a revoked license, as well as any use of the materials beyond the scope of an unrevoked license, may constitute copyright infringement and publisher reserves the right to take any and all action to protect its copyright in the materials.
9. Warranties: Publisher makes no representations or warranties with respect to the licensed material.
10. Indemnity: You hereby indemnify and agree to hold harmless publisher and CCC, and their respective officers, directors, employees and agents, from and against any and all claims arising out of your use of the licensed material other than as specifically authorized pursuant to this license.
11. No Transfer of License: This license is personal to you and may not be sublicensed,
assigned, or transferred by you to any other person without publisher's written permission.
12. No Amendment Except in Writing: This license may not be amended except in a writing signed by both parties (or, in the case of publisher, by CCC on publisher's behalf).
13. Objection to Contrary Terms: Publisher hereby objects to any terms contained in any purchase order, acknowledgment, check endorsement or other writing prepared by you, which terms are inconsistent with these terms and conditions or CCC's Billing and Payment terms and conditions. These terms and conditions, together with CCC's Billing and Payment terms and conditions (which are incorporated herein), comprise the entire agreement between you and publisher (and CCC) concerning this licensing transaction. In the event of any conflict between your obligations established by these terms and conditions and those established by CCC's Billing and Payment terms and conditions, these terms and conditions shall control.
14. Revocation: Elsevier or CopyrightClearanceCenter may deny the permissions described in this License at their sole discretion, for any reason or no reason, with a full refund payable to you. Notice of such denial will be made using the contact information provided by you. Failure to receive such notice will not alter or invalidate the denial. In no event will Elsevier or CopyrightClearanceCenter be responsible or liable for any costs, expenses or damage incurred by you as a result of a denial of your permission request, other than a refund of the amount(s) paid by you to Elsevier and/or CopyrightClearanceCenter for denied permissions.

## Oral presentation

Ionic liquids with the weakly coordinating anions: synthesis, properties and application
Bo Zhang, Su Li, Mirza Cokoja, Eberhardt Herdtweck, János Mink, Shu-Liang Zang and Fritz E. Kühn
The $16^{\text {th }}$ National Conference on Catalysis of China, 15-19 October 2012, Shenyang, China.

## Poster

Oxidation of sulfides to sulfoxides mediated by ionic liquids
Bo. Zhang, Ming-Dong Zhou, Mirza. Cokoja, János Mink, Shu-Liang Zang and Fritz E.

## Kühn

The $15^{\text {th }}$ International Congress on Catalysis (ICC), 01-06 July 2012, Munich, Germany.

Oxidation reactions catalyzed by polyoxomolybdate salts
Bo Zhang, Su Li, Alexander Pöthig, Mirza Cokoja, Shu-Liang Zang and Fritz E. Kühn The $16^{\text {th }}$ National Conference on Catalysis of China, 15-19 October 2012, Shenyang, China.

## Personal Information

## Education

Nov 2010 to Dec 2013

Sep 2007 to July 2010

Sep 2003 to July 2007

Ph. D. in Chemistry, Technische Universität München, with Prof. Fritz E. Kühn at Molecular Catalysis, Catalysis Research Center

Thesis title: Epxoidation and sulfoxidation mediated by ionic liquids
M. Sc. Prof. Shu-Liang Zang, Analytical Chemistry, Liaoning University, P. R. China

Thesis title: Methyltrioxorhenium (MTO) schiff-base complexes: synthesis, characterization and catalytic activity for epoxidation of olefins
B. Sc. Applied Chemistry, Shenyang Normal University, P. R. China

Thesis title: Study on the direct analysis of solid powder biological samples using fluorination assisted electrothermal vaporization inductively coupled plasma atomic emission spectrometry with PTFE slurry modifier
