### The rise of flexibility

Flexibility is gaining increasing attention and importance

Evolution of the number of publications containing the words "flexible" or "flexibility" in contrast with those containing "bandwidth" or "capacity" in four major IEEE journals and magazines on communication, with respect to the number of publications in 1995.

## Why?

- Networking today: new requirements from vertical industries and dynamically changing behavior of users and tenants
- Novel techniques to softwarize networks
- Less <u>explicitly</u> addressed: <u>flexibility</u> and hence <u>adaptation</u>

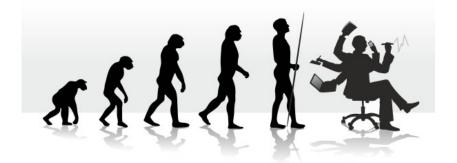

Image source: http://www.paleoplan.com

- Today, we will ...
  - ... present our definition of network flexibility and a flexibility measure, ...
  - ... give concrete use cases of how to apply ...
  - ... and show methods to speed up adaptations with ML.

#### Towards softwarized networks

The Internet is able to adapt its resources ...

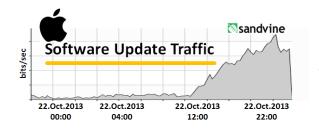

... somehow (best-effort, TCP elasticity, BGP, OSPF)

early-days simplicity

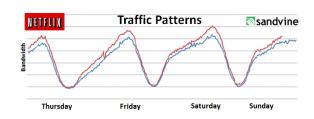

→ complex and ossified network system

#### very slow adaptation to new requirements

→ reaction to dynamic changes hardly possible

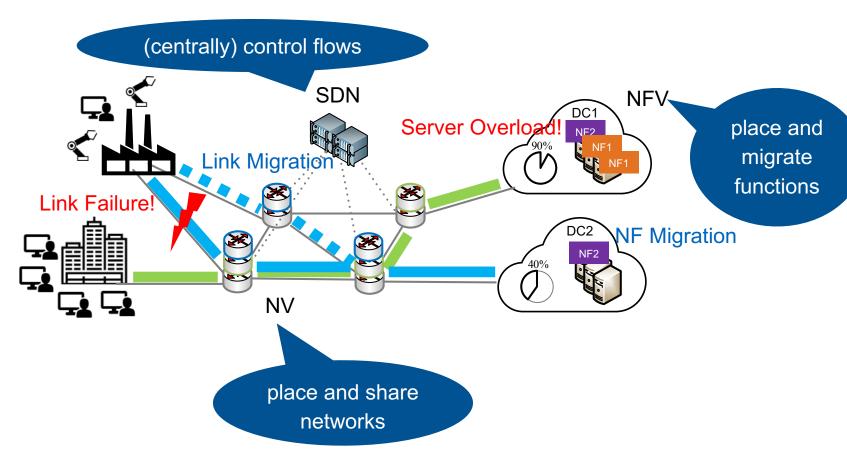

New concepts such as ...

Network Virtualization (NV), Network Function Virtualization (NFV), and Software Defined Networking (SDN)

Softwarized Networks

...promise to create and adapt networks and functions on demand in software

### All problems solved?

- Are we <u>fully flexible</u> already?
- How <u>far</u> can we go? What is the <u>optimal network design</u>?

#### We need

- a fundamental understanding of how to provide flexibility
- a quantitative measure for flexibility pro and contra certain designs

For networks, **flexibility** = ability to *support new requests* to change design requirements (traffic pattern, latencies,...) in a *timely* manner via adaptation of resources (topology, capacity, ...) if needed

This work is part of a project that has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 program grant agreement No 647158 – FlexNets (2015 – 2020).

### Why do we think flexibility analyis is important?

- A survey on 5G technology [1] reports "flexible and scalable network" as the top motivation for technology investment of 297 companies
- Enables operators to cover the future!
  - react to regulatory changes and fast arrival of new technologies
- A key decision factor between network designs
  - can be a tie-breaking decisive advantage for a certain network design
- For research and development
  - which technical concepts lead to more flexibility in network design?
    - → optimize networks for flexibility
    - → design guidelines for more flexible networks
- SoA: lack of a concrete definition and a quantitative analysis!

## How to define network flexibility? [3]

For network systems, **flexibility** = ability to *support new requests* to change design requirements (traffic pattern, latencies,...) in a *timely* manner via adaptation of resources (topology, capacity, ...) if needed

#### System?

communication network (topology, flows, node functions, resources)
 serving a certain objective (e.g. highly reliable communication)
 Note: in most cases, flexibility is not the objective

#### Request?

• "new challenges", e.g., new flows, new (virtual) topology or new latency requirements

Note: explicit list or via a distribution (e.g. flow arrivals)

So: the more requests are supported the more flexible a system is?

#### Time?

#### Time matters

"Heatposter" by Source. Licensed under Fair use via Wikipedia – http://en.wikipedia.org/wiki/File: Heatposter.jpg#/media/File:Heatposter.jpg

What Robert de Niro on *flexibility* in HEAT (1995):

"Don't get attached to anything you can't walk out on in 30 seconds flat if you feel the heat around the corner."

Not only the number of requests, but the *time* matters for flexibility!

how to consider for flexibility? how to speed up adaptation?

## How to define network flexibility?

For network systems, **flexibility** = ability to *support new requests* to change design requirements (traffic pattern, latencies,...) in a *timely* manner via adaptation of resources (topology, capacity, ...) if needed

#### System?

• communication network (topology, flows, node functions, resources) serving a certain objective (e.g. highly reliable communication)

#### Request?

• "new challenges", e.g., new flows, new (virtual) topology or new latency requirements

#### Time?

- the network may need to adapt the state of the topology, flows, functions, or resources → it should meet a time constraint
- the network may be designed in a way that it simply accommodates requests without adaptations → meets any time constraint

#### Flexibility aspects

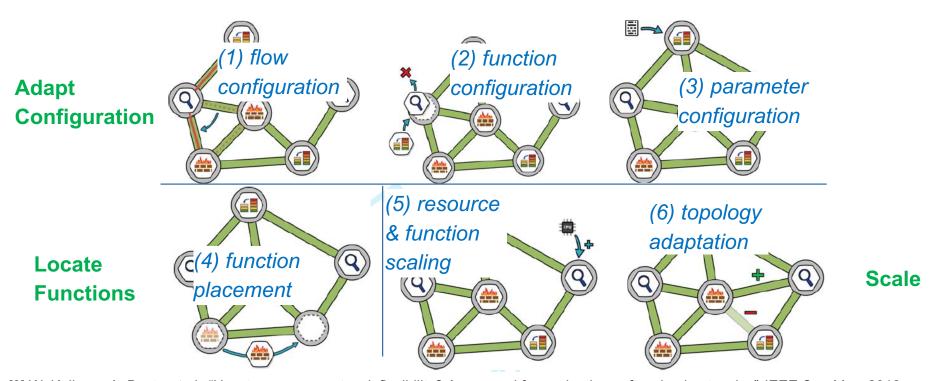

no single quality indicator for a Quality of Flexibilty (QoF)

similar to QoS: to be regarded by case

we propose: *flexibility aspects* [1, 3]

• similar as we do with QoS (rate, delay, throughput, jitter,...)

[3] W. Kellerer, A. Basta *et al.*, "How to measure network flexibility? A proposal for evaluating softwarized networks," *IEEE ComMag*, 2018.
[2] W. Kellerer, A. Basta, A. Blenk, Using a Flexibility Measure for Network Design Space Analysis of SDN and NFV, SWFAN'16, IEEE INFOCOM Workshop, April 2016.

## Flexibility aspects to technologies mapping

- SDN: is about flow control, also supports network resources scaling
- NFV: targets flexible placement, degrees of freedom in configuration and function scaling
- NV: targets flexible (virtual) topologies, also provides degrees of freedom for configuration and scaling of these (virtual) networks

Aspect (see Sec. III-B)	SDN	NFV	NV
Flow Configuration: flow steering	•		
Function Configuration: function programming		•	
Parameter Configuration: change function parameters		•	•
Function Placement: distribution, placement, chaining		•	•
Resource and Function Scaling: processing and storage capacity, number of fuctions	•	•	•
Topology Adaptation: (virtual) network adaptation			•

### Cost vs. Flexibility

- Flexibility has to be also evaluated against cost
- It is not clear if flexibility adds more cost overhead
- A flexible system can also achieve cost savings on the longer run
- > trade-off needs to be studied and evaluated
- We need to consider <u>all</u> different cost factors

Resources (CAPEX)	Operation (OPEX)	Adaptation/Migration	SLA
resource overhead	control, data plane throughput	synchronization overhead	fines
network complexity	control, data plane latency	configuration latency	flow interruption
software complexity	energy consumption	topology adaptation latency	network interruption

[3] W. Kellerer, A. Basta et al., "How to measure network flexibility? A proposal for evaluating softwarized networks," IEEE ComMag, 2018.

## Key takeaways – part 1

## Flexibility matters!

- new requirements for networking research include flexibility
- network softwarization (SDN, NFV, NV) provides flexibility

## Flexibility definition is important!

- for a meaningful system analysis and comparison
- for a trade-off evaluation with performance and cost
- to design for flexibility

## We need a measure!

#### Flexibility qualitiative measure exercise

- Which tool is more flexible?
  - re-configuration shows more potential to be more flexible
- When can both exihbit the same flexibility?
  - maybe there is no need to change -> probability of requests make a difference
  - maybe both cannot satsify my requests → infeasible
- When can the re-configurable tool be less flexible?
  - adaptation time 

    might make the re-configurable object not very useful

## Flexibility Measure – Proposal

constraint on max.

 $\varphi_{T}^{aspect}(S) = \frac{|supported \ new \ requests \ within \ time \ constraint \ T|}{|given \ new \ requests|}$ 

 fraction of the number of new requests that can be supported in a time interval T of all given new requests [3]

$$\varphi_{T}$$

$$\varphi_{T}$$

$$100\%$$

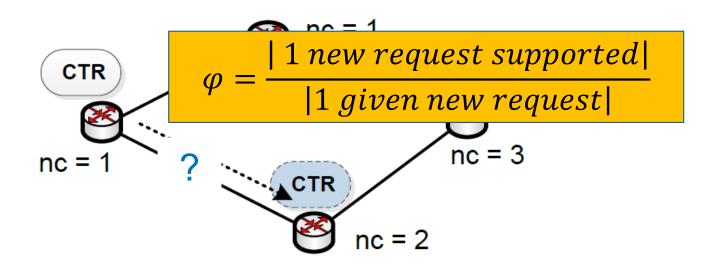

$$|given \ new \ requests|$$

$$T$$

## A simple illustration (1)

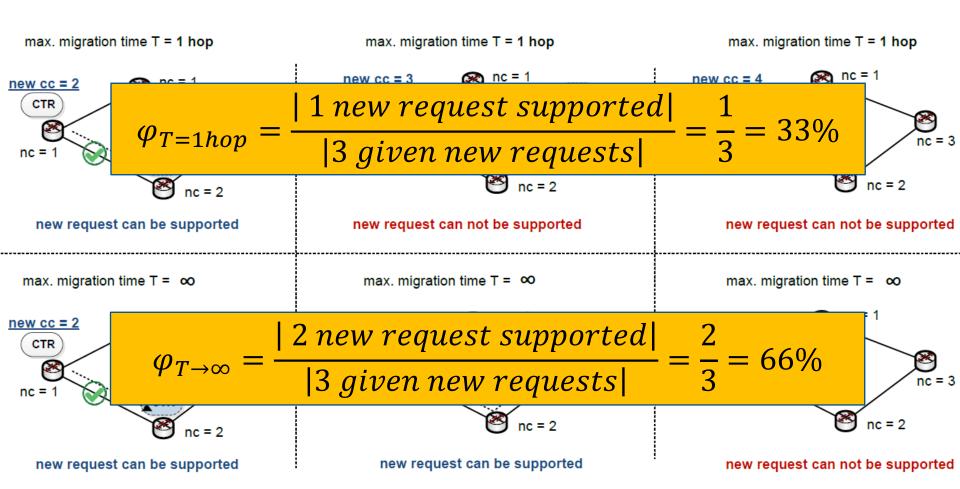

- New request to an SDN network: Controller Capacity (cc) is increased
- Can such new request be supported?
   e.g. by migrating the controller to a node with higher Node Capacity (nc)
- BUT: migration time cannot exceed "1 hop" (T)

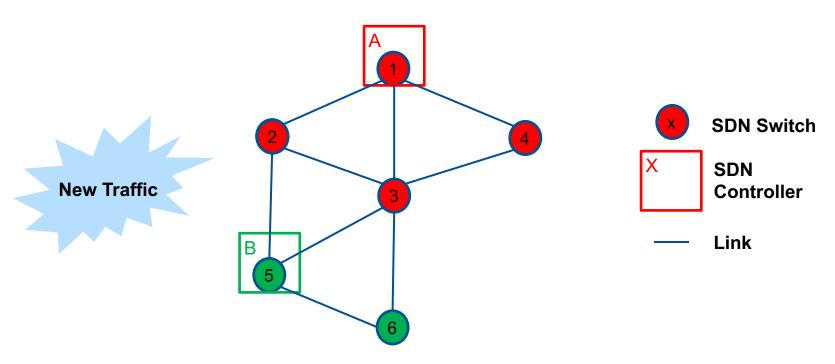

## A simple illustration (2): more requests

### **Case study 1: Dynamic Controller Placement**

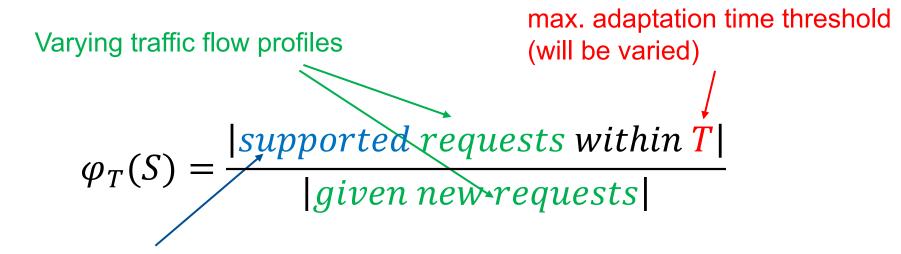

- Traffic fluctuations require control plane to adapt in order to achieve better control performance → Dynamic Control Plane [4]
  - SDN controller migration
  - SDN switch reassignment

Case Study	Flexibility Aspect	New Request	Flexibility Measure	System Objective	Cost in focus
dynamic SDN	function placement	new flow arrival	fraction of successful	control performance:	operation latency (OPEX):
controller placement		(from distribution)	controller placements	(min. avg. flow setup time)	avg. flow setup time

### Case study 1: Dynamic Controller Placement

Application of the flexibility measure

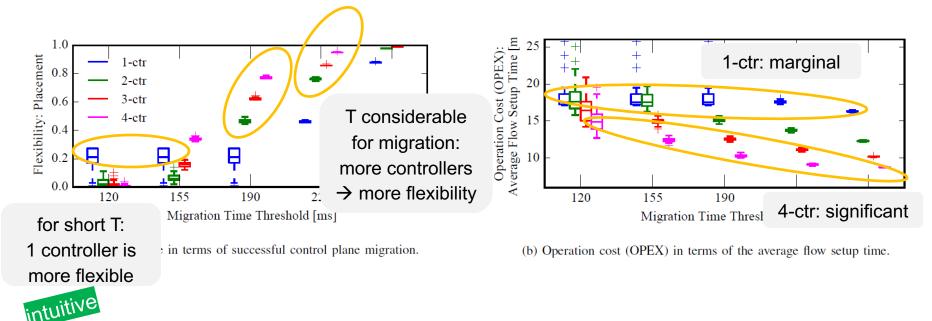

SDN controller migration and switch reassignment can be done within T

- Flexibility → Migration Success Ratio
  - Calculate controller migration and switch reassignment time T migration
  - If T\_migration smaller than T → count as a supported request

## Case study 1: Dynamic Controller Placement

- More controllers (larger migration time threshold) → higher flexibility
- Single controller case: more flexible for tight time threshold as probability that single controller stays in optimal location is high
  - 1 controller → marginal performance improvement vs. adaptation T
  - 4 controllers → significant performance improvement vs. adaptation T
  - However, if we consider all cost factors, we can reach a trade-off!

## Case study 2: SDN Resilience

- Flexibility aspect of flow configuration for a resilience scenario in an SDN network under a given recovery time threshold T [3].
- Compare 3 systems: 1:1 protection vs 1+1 protection vs restoration
- New requests: all possible single and dual link failures
- Objective: system recovery
- Flexibility measure: fraction of recoverable failures

Case Study	Flexibility Aspect	New Request	Flexibility Measure	System Objective	Cost in focus
failure recovery in SDN (protection vs. restoration)	flow configuration	all possible single and dual failures	fraction of recoverable failures	system recovery: (single and dual failures)	resources overhead (CAPEX): node and link reservation

## Case study 2: SDN Resilience

#### 1:1 protection

- primary and backup paths pre-calculated
- backup path is inactive
- need switching time between primary and backup in case of a failure

#### 1+1 protection

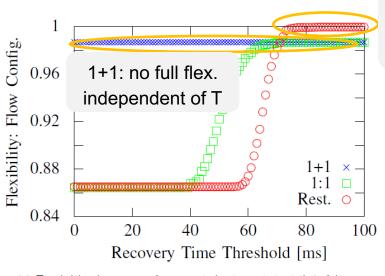

- primary and backup paths pre-calculated
- primary and backup paths are both active
- recovery time is almost instantaneous!

#### Restoration

- no backup path in advance
- switch detect failure → controller informed → re-routes affected flows
- recovery time is very critical

## Case study 2: SDN Resilience

restoration: full flex. needs enough T

	Resources Cost (CAPEX)			
	Node reservation:	Link reservation:		
	Avg. number of flow table entries	Number of required links		
1 + 1	11.78	13038		
1:1	11.78	13038		
Rest.	5.05	5400		

#### 1+1 can not reach full flexibility

- However, 1+1 is obviously **independent** of **recovery time**Restoration can cover **all failures** if given enough recovery time
- Protection imposes more than 2x capex overhead than restoration
- Again, if we consider all cost factors, we can reach a trade-off!

<sup>(</sup>a) Flexibility in terms of covered single and dual link failures.

<sup>(</sup>b) System resources cost (CAPEX) in terms of nodes and links used for reservation.

## **Key takeaways – part 2**

- One way to measure flexibility
   so far only relatively between multiple systems
- Results can be less intuitive than one might think
- Flexibility tends to decrease cost but also comes at a cost
- Measure can be used to design for flexibility
- Adaptation time is important for a flexibile system

#### **Time matters**

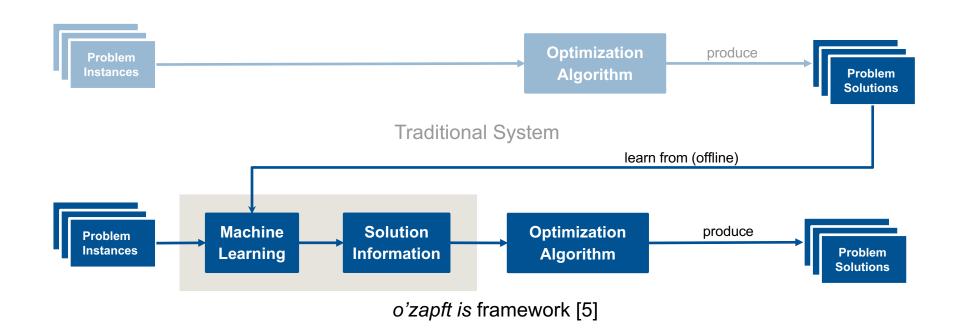

- Adaptation time is very important for a flexibility measure
- Adaptation examples:
  - Function placement, e.g., SDN controller
  - (re-)embedding of virtual networks/flows, e.g. for resilience
- How can we speedup?
- Yet another heuristic for a specific case study?

#### We propose:

- Keep your favourite optimization algorithms and
- Boost your network algorithm with ML preprocessing

# How can we boost the solving of the related optimization problems?

State-of-the-art: Neglects produced data!

Idea: Use problem/solution data generated by algorithms regularly solving problems

# Case Study: Predicting Acceptance Probabilities of VNE Requests

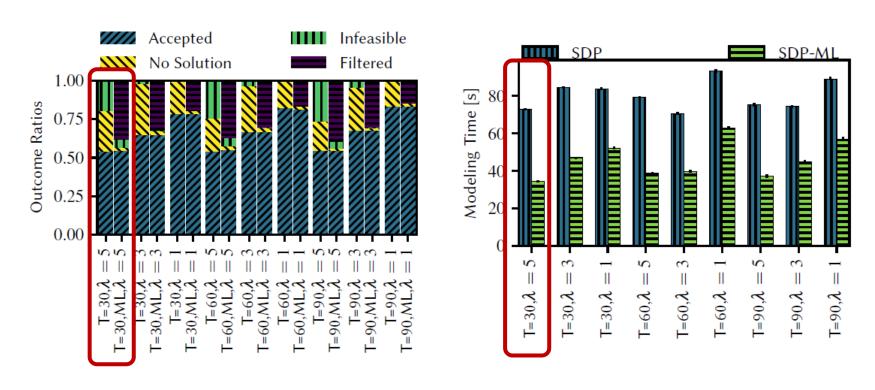

- Supervised learning: use data with accepted and rejected requests! Offline training!
- Recurrent neural network (RNN) for classification
- Filter infeasible and requests with unacceptable algorithm runtime ("no solution")

## Can we speed-up optimal algorithms using admission control?

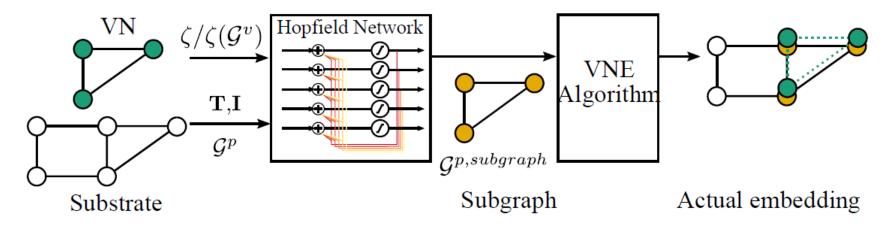

Efficient Filtering of infeasible and unacceptable requests Efficient saving of model creation time

### **Latest Results: Neurovine [6]**

Hopfield neural network to preprocess (subgraph extraction) VNE algorithms

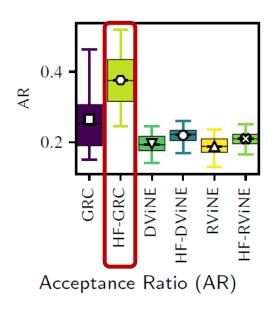

– tailored filtering

 Idea: Extract subgraph with physical nodes close to each other and high available capacities

# Neurovine: Efficiency on Real Network Topologies

- VNE algorithms (GRC, DViNE, RViNE) vs. Hopfield variants (HF-GRC, HF-DViNE, HF-RViNE)
- NeuroViNE accepts more networks with less costs

### **Key Takeaways & outlook**

#### Flexibility matters!

We propose a

#### definition and measure for flexibility

- to compare flexible systems
- to explicitly design for flexibility
- Adaptation/optimization time is important for flexible systems
   Speedup optimization algorithms through
   Machine Learning-based preprocessing
- Recent work: Empowerment concept to design for flexibility [7]
