1. Introduction

The design of distributed protocols for networked multi-agent systems has been one of the most active research topics in the field of systems and control over the last two decades, see e.g. Cao, Yu, Ren, and Chen (2013) or Olfati-Saber and Murray (2004). This is partly due to the broad range of applications of multi-agent systems, e.g. smart grids (Dörfler, Chertkov, & Bullo, 2013), formation control (Oh, Park, & Ahn, 2015; Yang, Sun, Cao, Fang, & Chen, 2019), and intelligent transportation systems (Besselink & Johansson, 2017). One of the challenging problems in the context of linear multi-agent systems is the problem of developing distributed protocols to minimize given quadratic cost criteria while the agents reach a common goal, e.g., synchronization. Due to the structural constraints that are imposed on the control laws by the communication topology, such optimal control problems are difficult to solve. These structural constraints make distributed optimal control problems non-convex, and it is unclear under what conditions optimal solutions exist in general.

In the existing literature, many efforts have been devoted to addressing distributed linear quadratic optimal control problems.

In Borrelli and Keviczky (2008), suboptimal distributed stabilizing controllers were computed to stabilize multi-agent networks with identical agent dynamics subject to a global linear quadratic cost functional. For a network of agents with single integrator dynamics, an explicit expression for the optimal gain was given in Cao and Ren (2010), see also Jiao, Trentelman, and Camlibel (2020c). In Movric and Lewis (2014) and Zhang, Feng, Yang, and Liang (2015), a distributed linear quadratic control problem was dealt with using an inverse optimality approach. This approach was further employed in Nguyen (2017) to design reduced order controllers. Recently, also in Jiao, Trentelman, and Camlibel (2020b), the suboptimal distributed LQ problem was considered. In parallel to the above, much work has been put into the problem of distributed $\mathcal{H}_2$ optimal control. Given a particular global $\mathcal{H}_2$ cost functional, Li and Duan (2014) and Li, Duan, and Chen (2011) proposed suboptimal distributed stabilizing protocols involving static state feedback for multi-agent systems with undirected graphs. Later on, in Wang, Duan, Li, and Wen (2014) these results were generalized to directed graphs. For a given $\mathcal{H}_2$ cost criterion that penalizes the weighted differences between the outputs of the communicating agents, in Jiao, Trentelman, and Camlibel (2018) a suboptimal distributed synchronizing protocol based on static relative state feedback was established.

In the past, also the design of structured controllers for large-scale systems has attracted much attention. In Rotkowitz and Lall (2006), the notion of quadratic invariance was adopted to develop decentralized controllers that minimize the performance of the feedback system with constraints on the controller structure. In Lin, Fardad, and Jovanović (2013), the so called alternating direction method of multipliers was adopted to design sparse...
feedback gains that minimize an $H_2$ performance. In Fattahi, Fazelnia, Lavaei, and Arcak (2019), conditions were provided under which, for a given optimal centralized controller, a suboptimal distributed controller exists so that the resulting closed loop state and input trajectories are close in a certain sense.

The distributed $H_2$ optimal control problem for multi-agent systems by dynamic output feedback is to find an optimal distributed dynamic protocol that achieves synchronization for the controlled network and that minimizes the $H_2$ cost functional. This problem, however, is a non-convex optimization problem, and therefore it is unclear whether such optimal protocol exists, or whether a closed form solution can be given. Therefore, in the present paper, we look at an alternative version of this problem that requires only suboptimality. More precisely, we extend our preliminary results from jiao et al. (2018) on static relative state feedback to the general case of dynamic protocols using relative measurement outputs. The main contributions of this paper are the following.

1) We solve the open problem of finding, for a single continuous-time linear system, a separation principle based $H_2$ suboptimal dynamic output feedback controller. This result extends the recent result in Haesaert, Weiland, and Scherer (2018) on the separation principle in suboptimal $H_2$ control for discrete-time systems.

2) Based on the above result, we provide a method for computing $H_2$ suboptimal distributed dynamic output feedback protocols for linear multi-agent systems.

The outline of this paper is as follows. In Section 2, we will provide some notation and graph theory used throughout this paper. In Section 3, we will formulate the suboptimal distributed $H_2$ control problem by dynamic output feedback for linear multi-agent systems. In order to solve this problem, in Section 4, we will first study suboptimal $H_2$ control by dynamic output feedback for a single linear system. In Section 5 we will then treat the problem introduced in Section 3. To illustrate our method, a simulation example is provided in Section 6. Finally, Section 7 concludes this paper.

2. Preliminaries

2.1. Notation

In this paper, the field of real numbers is denoted by $\mathbb{R}$ and the space of $n$ dimensional real vectors is denoted by $\mathbb{R}^n$. We denote by $\mathbf{1}_n \in \mathbb{R}^n$ the vector with all its entries equal to 1 and we denote by $I_n$ the identity matrix of dimension $n \times n$. For a symmetric matrix $P$, we denote $P > 0$ if $P$ is positive definite and $P < 0$ if $P$ is negative definite. The trace of a square matrix $A$ is denoted by $tr(A)$. A matrix is called Hurwitz if all its eigenvalues have negative real parts. We denote by diag$(d_1, d_2, \ldots, d_n)$ the $n \times n$ diagonal matrix with $d_1, d_2, \ldots, d_n$ on the diagonal. For given matrices $M_1, M_2, \ldots, M_n$, we denote by blockdiag$(M_1, M_2, \ldots, M_n)$ the block diagonal matrix with diagonal blocks $M_i$. The Kronecker product of two matrices $A$ and $B$ is denoted by $A \otimes B$.

2.2. Graph theory

A directed weighted graph is denoted by $G = (\mathcal{V}, \mathcal{E}, A)$ with node set $\mathcal{V} = \{1, 2, \ldots, N\}$ and edge set $\mathcal{E} = \{e_1, e_2, \ldots, e_{\mathcal{E}}\}$ satisfying $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$, and where $A = [a_{ij}]$ is the adjacency matrix with nonnegative elements $a_{ij}$, called the edge weights. If $(i, j) \in \mathcal{E}$ we have $a_{ij} > 0$. If $(i, j) \notin \mathcal{E}$ we have $a_{ij} = 0$.

A graph is called undirected if $a_{ij} = a_{ji}$ for all $i, j$. It is called simple if $a_{ii} = 0$ for all $i$. A simple undirected graph is called connected if for each pair of nodes $i$ and $j$ there exists a path from $i$ to $j$. Given a simple undirected weighted graph $G$, the degree matrix of $G$ is the diagonal matrix, given by $D = \text{diag}(d_1, d_2, \ldots, d_N)$ with $d_i = \sum_j a_{ij}$. The Laplacian matrix is defined as $L = D - A$. The Laplacian matrix of an undirected graph is symmetric and has only real nonnegative eigenvalues. A simple undirected weighted graph is connected if and only if its Laplacian matrix $L$ has a simple eigenvalue at 0. In that case there exists an orthogonal matrix $U$ such that $U^T L U = \text{diag}(0, \lambda_2, \ldots, \lambda_N)$ with $0 < \lambda_2 \leq \cdots \leq \lambda_N$. Throughout this paper, we will be standing assumption that the communication among the agents of the network is represented by a connected, simple undirected weighted graph.

A simple undirected weighted graph obviously has an even number of edges $M$. Define $K := \frac{1}{2} M$. For such graph, an associated incidence matrix $R \in \mathbb{R}^{N \times K}$ is defined as a matrix $R = (r_1, r_2, \ldots, r_K)$ with columns $r_k \in \mathbb{R}^N$. Each column $r_k$ corresponds to exactly one pair of edges $e_k = \{[i, j], (j, i)\}$, and the $i$th and $j$th entry of $r_k$ are equal to $\pm 1$, while they do not take the same value. The remaining entries of $r_k$ are equal to 0. We also define the matrix $W = \text{diag}(w_1, w_2, \ldots, w_K)$ (1) as the $K \times K$ diagonal matrix, where $w_k$ is the weight on each of the edges in $e_k$ for $k = 1, 2, \ldots, K$. The relation between the Laplacian matrix and the incidence matrix is captured by $L = R W^T$ (Monshizadeh, Trentelman, & Camlibel, 2014).

3. Problem formulation

In this paper, we consider a homogeneous multi-agent system consisting of $N$ identical agents, where the underlying network graph is a connected, simple undirected weighted graph with associated adjacency matrix $A$ and Laplacian matrix $L$. The dynamics of the $i$th agent is represented by a finite-dimensional linear time-invariant system

$$\dot{x}_i = A x_i + B u_i + E d_i,$$

$$y_i = C x_i + D d_i, \quad i = 1, 2, \ldots, N,$$

$$z_i = C_2 x_i + D_2 u_i,$$

where $x_i \in \mathbb{R}^n$ is the state, $u_i \in \mathbb{R}^m$ is the coupling input, $d_i \in \mathbb{R}^q$ is an unknown external disturbance, $y_i \in \mathbb{R}^p$ is the measured output and $z_i \in \mathbb{R}^p$ is the output to be controlled. The matrices $A$, $B$, $C_1$, $C_2$, $D_1$, $D_2$ and $E$ are of compatible dimensions. Throughout this paper we assume that the pair $(A, B)$ is stabilizable and the pair $(C_1, A)$ is detectable. The agents (2) are to be interconnected by means of a dynamic output feedback protocol. Following Trentelman, Takaba, and Monshizadeh (2013) and Zhang, Trentelman, and Scherpen (2016), we consider observer based dynamic protocols of the form

$$\dot{\tilde{u}}_i = A \tilde{u}_i + B \sum_{j=1}^N a_{ij}(u_i - u_j) + G \left( \sum_{j=1}^N a_{ij}(y_i - y_j) - C_1 \tilde{u}_j \right),$$

$$u_i = F \tilde{u}_i, \quad i = 1, 2, \ldots, N,$$

where $G \in \mathbb{R}^{n \times p}$ and $F \in \mathbb{R}^{m \times n}$ are local gains to be designed. We briefly explain the structure of this protocol. Each local controller of the protocol (3) observes the weighted sum of the relative input signals $\sum_{j=1}^N a_{ij}(u_i - u_j)$ and the weighted sum of the disagreements between the measured output signals $\sum_{j=1}^N a_{ij}(y_i - y_j)$. The first equation in (3) in fact represents an asymptotic observer for the weighted sum of the relative state of agent $i$, and the state of this observer is an estimate of this value. Note that, for the error $e_i := u_i - \sum_{j=1}^N a_{ij}(x_i - x_j)$, the error dynamics is $\dot{e}_i = (A - GC_1)e_i + \sum_{j=1}^N a_{ij}(GD_1 - E(d_i - d_j))$. An estimate of the
weighted sum of the relative states of each agent is then fed back to this agent using a static gain.

Denote by $\mathbf{x} = (x_1^T, x_2^T, \ldots, x_N^T)^T$ the aggregate state vector and likewise define $u, y, \mathbf{z}, \mathbf{d}$ and $\mathbf{w}$. The multi-agent system (2) can then be written in compact form as

$$
\dot{\mathbf{x}} = (I_N \otimes A)\mathbf{x} + (I_N \otimes B)u + (I_N \otimes E)d,
$$

$$
y = (I_N \otimes C_1)\mathbf{x} + (I_N \otimes D_1)\mathbf{d},
$$

$$
\mathbf{z} = (I_N \otimes C_2)\mathbf{x} + (I_N \otimes D_2)u,
$$

and the dynamic protocol (3) is represented by

$$
\mathbf{w} = (I_N \otimes (A - GC_1) + L \otimes BF)\mathbf{w} + (L \otimes G)y.
$$

By interconnecting the network (4) using the dynamic protocol (5), we obtain the controlled network

$$
\begin{align*}
\dot{\mathbf{x}} &= \left( I_N \otimes A \right) \mathbf{x} + \left( I_N \otimes BF \right) \mathbf{w} + \left( I_N \otimes E \right) \mathbf{d}, \\
y &= \left( I_N \otimes C_1 \right) \mathbf{x} + \left( I_N \otimes D_1 \right) \mathbf{d}, \\
\mathbf{z} &= \left( I_N \otimes C_2 \right) \mathbf{x} + \left( I_N \otimes D_2 \right) \mathbf{u}.
\end{align*}
$$

Next, the associated global $H_2$ cost functional is defined to be the squared $H_2$-norm of the closed loop impulse response, and is given by

$$
J(F, G) := \int_0^\infty tr\left[ T_{F,G}(t)T_{F,G}(t)^\top \right] dt.
$$

The distributed $H_2$ optimal control problem by dynamic output feedback is the problem of minimizing (10) over all dynamic protocols of the form (5) that achieve synchronization for the network. Unfortunately, due to the particular form of the protocol (5), this optimization problem is, in general, non-convex and difficult to solve, and a closed form solution has not been provided in the literature up to now. Therefore, instead of trying to find an optimal solution, in this paper we will address a suboptimality version of the problem. More specifically, we will design synchronizing dynamic protocols (5) that guarantee the associated cost (10) to be smaller than an a priori given upper bound. More concretely, the problem that we will address is the following:

**Problem 1.** Let $\gamma > 0$ be a given tolerance. Design local gains $F \in \mathbb{R}^{m \times n}$ and $G \in \mathbb{R}^{n \times r}$ such that the dynamic protocol (5) achieves $J(F, G) \leq \gamma$ and synchronizes the network.

Before we address Problem 1, we will first study the suboptimal $H_2$ control problem by dynamic output feedback for a single linear system. In that way, we will collect the required preliminary results to treat the actual suboptimal distributed $H_2$ control problem for multi-agent systems.

## 4. Suboptimal $H_2$ control by dynamic output feedback for linear systems

In this section, we will discuss the suboptimal $H_2$ control problem by dynamic output feedback for a single linear system. This problem has been dealt with before, see e.g. Haesaert et al. (2018), Scherer, Gahinet, and Chilali (1997), Scherer and Weiland (2000) or Skelton, Iwasaki, and Grigoriadis (1997). In particular, in Haesaert et al. (2018), the separation principle for suboptimal $H_2$ control for discrete-time linear systems was established. Here, we will establish the analogue of that result for the continuous-time case.

Consider the linear system

$$
\dot{x} = Ax + Bu + Ed, \\
y = Cx + D_1d, \\
z = C_2x + D_2u,
$$

where $x \in \mathbb{R}^n$ is the state, $u \in \mathbb{R}^m$ the control input, $d \in \mathbb{R}^q$ an unknown external disturbance, $y \in \mathbb{R}^r$ the measured output, and $z \in \mathbb{R}^p$ the output to be controlled. The matrices $A, B, C_1, C_2, D_2$ and $E$ have compatible dimensions. In this section, we assume that the pair $(A, B)$ is stabilizable and the pair $(C_1, A)$ is detectable. Moreover, we consider dynamic output feedback controllers of the form

$$
\dot{w} = Aw + Bu + G(y - \hat{C}_1w), \\
u = Fw,
$$

where $w \in \mathbb{R}^n$ is the state of the controller, and $F \in \mathbb{R}^{m \times n}$ and $G \in \mathbb{R}^{n \times r}$ are gain matrices to be designed. By interconnecting the controller (12) and the system (11), we obtain the controlled system

$$
\begin{align*}
\dot{x} &= \bar{A}x + \bar{B}d, \\
\dot{w} &= \bar{C}_1\mathbf{w} + \bar{D}_1\mathbf{d}, \\
z &= (\bar{C}_2 \bar{D}_2)\mathbf{w}.
\end{align*}
$$
Denote $A_e = \begin{pmatrix} A & BF \\ GC_1 & A + BF - GC_1 \end{pmatrix}$, $E_e = \begin{pmatrix} E \\ GD_1 \end{pmatrix}$, $C_e = (C_2 \ D_2 F)$. Then the impulse response matrix from the disturbance $d$ to the output $z$ is given by $T_{F,G}(t) = C_e e^{A_e t} E_e$. Next, we introduce the associated $H_2$ cost functional, given by

$$J(F, G) := \int_0^\infty \text{tr} [T_{F,G}^T(t) T_{F,G}(t)] \, dt. \quad (14)$$

We are interested in the problem of finding a controller of the form (12) such that the controlled system (13) is internally stable and the associated cost (14) is smaller than an a priori given upper bound.

The following lemma is an extension of Theorem 6 in Haesaert et al. (2018). It provides conditions under which the controller (12) with gain matrices $F$ and $G = Q C_1^T$ is stabilizable for the continuous-time system (11), where $Q$ is a particular real symmetric solution of a given Riccati inequality. The result shows that the separation principle is also applicable in the context of suboptimal $H_2$ control for continuous-time systems.

**Lemma 2.** Consider the system (11) with associated cost functional (14). Assume that $D_1 D_2^T = 0$, $D_1^T C_2 = 0$, $D_1^T D_2 > 0$. Let $F \in \mathbb{R}^{m \times n}$. Suppose that there exists $P > 0$ satisfying

$$(A + BF)^T P + P (A + BF) + (C_2^T + D_2^T F)(C_2 + D_2 F) < 0. \quad (15)$$

Let $Q > 0$ be a solution of the Riccati inequality

$$A^T Q + Q A - Q C_1^T C_2 Q + E E^T < 0. \quad (16)$$

If, moreover, the inequality

$$\text{tr} \left( [C_1^T Q C_2] - [C_2^T C_2] \right) < \gamma \quad (17)$$

holds, then the controller (12) with the gains $F$ and $G = Q C_1^T$ yields an internally stable closed loop system (13), and it is suboptimal, i.e. $J(F, G) < \gamma$.

A proof can be given along the lines of the proof of Theorem 6 in Haesaert et al. (2018). For a complete proof of Lemma 2, we refer to Jiao, Trentelman, and Camlibel (2020a). Note that a result similar to Lemma 2 can also be formulated under the assumptions $D_1 D_1^T > 0$ and $D_1 D_2 > 0$ alone. The assumptions $D_1 D_2^T = 0$, $D_1^T C_2 = 0$ and $D_1^T D_2 = I_n$ are made here to simplify the notation, and can be easily removed.

We are now ready to deal with the suboptimal distributed $H_2$ control problem by dynamic output feedback for multi-agent systems.

**5. Suboptimal distributed $H_2$ control for multi-agent systems by dynamic output feedback**

In this section, we will address Problem 1. For the multi-agent system (2), we will establish a design method for local gains $F$ and $G$ such that the protocol (3) achieves $J(F, G) < \gamma$ and synchronizes the network (6).

Let $U$ be an orthogonal matrix such that $U^T U = A = \text{diag}(0, \lambda_2, \ldots, \lambda_N)$ with $0 < \lambda_2 \leq \cdots \leq \lambda_N$ the eigenvalues of the Laplacian matrix. We apply the state transformation

$$\begin{pmatrix} \tilde{x} \\ \tilde{w} \end{pmatrix} = \begin{pmatrix} U^T \otimes I_n \\ 0 \end{pmatrix} \begin{pmatrix} x \\ w \end{pmatrix}. \quad (18)$$

Then the controlled network (6) with the associated output (8) is also represented by

$$\begin{pmatrix} \tilde{\xi} \\ \tilde{\omega} \end{pmatrix} = \begin{pmatrix} I_n \otimes A & I_n \otimes BF \\ A \otimes GC_1 & I_n \otimes (A - GC_1) + A \otimes BF \end{pmatrix} \begin{pmatrix} \tilde{x} \\ \tilde{w} \end{pmatrix} + \begin{pmatrix} U^T \otimes E \\ U^T L \otimes GD_1 \end{pmatrix} d. \quad (19)$$

Denote

$$\begin{align*}
\tilde{A}_e &= \begin{pmatrix} I_n \otimes A & I_n \otimes BF \\ A \otimes GC_1 & I_n \otimes (A - GC_1) + A \otimes BF \end{pmatrix}, \\
\tilde{C}_e &= \begin{pmatrix} \frac{w^T R^T U}{2} + C_2 \end{pmatrix}, \\
\tilde{E}_e &= \begin{pmatrix} \frac{U^T \otimes E}{2} \\ U^T L \otimes GD_1 \end{pmatrix}.
\end{align*}$$

Obviously, the impulse response matrix $T_{F,G}(t)$ given by (9) is then equal to $\tilde{C}_e e^{\tilde{A}_e t} \tilde{E}_e$.

In order to proceed, we now introduce the $N-1$ auxiliary linear systems

$$\begin{align*}
\dot{\xi}_i &= \frac{\lambda_i}{\gamma} \dot{\omega}_i + \frac{\lambda_i}{\gamma} B F, \\
\dot{\omega}_i &= C_1 \xi_i + D_1 \dot{\omega}_i, \\
\eta_i &= \frac{\sqrt{\lambda_i}}{\lambda_i} \xi_i + \frac{\sqrt{\lambda_i}}{\lambda_i} \omega_i, \\
is &\equiv 2, 3, \ldots, N.
\end{align*}$$

with gain matrices $F$ and $G$. By interconnecting (21) and (20), we obtain the $N-1$ closed loop systems

$$\begin{align*}
\begin{pmatrix} \dot{\xi}_i \\ \dot{\omega}_i \\ \eta_i \end{pmatrix} &= \begin{pmatrix} A \\ A - GC_1 + \lambda_i BF \end{pmatrix} \begin{pmatrix} \xi_i \\ \omega_i \\ \eta_i \end{pmatrix} + \begin{pmatrix} E \\ GD_1 \end{pmatrix} \delta_i, \\
\delta_i &= \frac{\sqrt{\lambda_i}}{\lambda_i} \xi_i + \frac{\sqrt{\lambda_i}}{\lambda_i} \omega_i, \\
\eta_i &= \frac{\sqrt{\lambda_i}}{\lambda_i} \eta_i.
\end{align*} \quad (22)$$

for $i = 2, 3, \ldots, N$. The impulse response matrix of (22) from the disturbance $\delta_i$ to the output $\eta_i$ is equal to

$$T_{I,G}(t) = \tilde{C}_i e^{\tilde{A}_i t} \tilde{E}_i \quad (23)$$

with $\tilde{A}_i = \begin{pmatrix} A \\ A - GC_1 + \lambda_i BF \end{pmatrix}$, $\tilde{E}_i = \begin{pmatrix} E \\ GD_1 \end{pmatrix}$, $\tilde{C}_i = \frac{\lambda_i}{\sqrt{\lambda_i} \lambda_i} \tilde{C}_2$. Furthermore, for each system (20) the associated $H_2$ cost functional is given by

$$J(F, G) := \int_0^\infty \text{tr} [T_{I,G}^T(t) T_{I,G}(t)] \, dt. \quad (24)$$

Then we have the following lemma:

**Lemma 3.** Let $F \in \mathbb{R}^{m \times n}$ and $G \in \mathbb{R}^{n \times r}$. Then the dynamic protocol (3) with gain matrices $F$ and $G$ achieves synchronization for the network (6) if and only if for each $i = 2, 3, \ldots, N$ the controller (21) with gain matrices $F$ and $G$ internally stabilizes the network (20). Moreover, we have

$$J(F, G) = \sum_{i=2}^N J_i(F, G). \quad (25)$$

**Proof.** It follows immediately from Trentelman et al. (2013, Lemmas 3.2 and 3.3) that the dynamic protocol (3) achieves synchronization for the network (6) if and only if for each $i = 2, 3, \ldots, N$ the system (20) is internally stabilized by the controller (21). Next, we prove (25). Let $F$ and $G$ be such that synchronization is achieved. Then we have

$$J(F, G) = \int_0^\infty \text{tr} \left( \tilde{E}_i^T e^{\tilde{A}_i t} \tilde{C}_i e^{\tilde{A}_i t} \tilde{E}_i \right) \, dt.$$
where
\[ A_i = \begin{pmatrix} A & BF \\ λ_i C_1 & A - C_1 G + λ_i BF \end{pmatrix}, \quad C_i = \begin{pmatrix} \sqrt{λ_i} C_2 & \sqrt{λ_i} D_2 F \end{pmatrix}, \quad E_i = \begin{pmatrix} E \\ λ_i G D_1 \end{pmatrix}. \]

Let \( \sum_{i=2}^{N} J_i(T, F, G) \) be a given tolerance. Assume that \( D_1 E^T = 0, D_1^T C_0 = 0, D_1 D_2^T = I, D_2 D_1^T = I_m \). Then there exists \( P \) such that the inequalities
\[ (A + λ_i BF)^T P_i + P_i (A + λ_i BF) + (\sqrt{λ_i} C_2 + λ_i \sqrt{λ_i} D_2 F)^T (\sqrt{λ_i} C_2 + λ_i \sqrt{λ_i} D_2 F) < 0, \]
\[ A Q + QA^T - Q C_i^T C_i Q + EE^T < 0, \]
\[ \sum_{i=2}^{N} \{ (C_i Q P_i Q C_i^T)^T + λ_i tr(C_i Q P_i Q C_i^T) \} < γ. \]

hold. Then for each \( i = 2, 3, \ldots, N \), the controller (21) with gain matrices \( F \) and \( G = QC_i^T \) internally stabilizes the system (20), and, moreover, \( \sum_{i=2}^{N} J_i(T, F, G) < γ \).

Theorem 5. Let \( γ > 0 \) be a given tolerance. Assume that \( D_1 E^T = 0, D_1^T C_0 = 0, D_1 D_2^T = I, D_2 D_1^T = I_m \). Let \( Q > 0 \) satisfy
\[ AQ + QA^T - QC_i^T C_i Q + EE^T < 0. \]

Let \( c \) be any real number such that \( 0 < c < \frac{γ}{N-1} \). We distinguish two cases:

(i) if
\[ \frac{2}{λ_i^2 + λ_2 λ_N + λ_N^2} \leq c < \frac{2}{λ_i^2 + λ_2 λ_N + λ_N^2}, \]
then there exists \( P > 0 \) satisfying
\[ A^T P + PA + (c^2 λ_2^3 - 2c λ_N) P B B^T P + λ_N C_2^T C_2 < 0. \]

(ii) if
\[ 0 < c < \frac{2}{λ_i^2 + λ_2 λ_N + λ_N^2}, \]
then there exists \( P > 0 \) satisfying
\[ A^T P + PA + (c^2 λ_2^3 - 2c λ_N) P B B^T P + λ_N C_2^T C_2 < 0. \]

In both cases, if in addition \( P \) and \( Q \) satisfy
\[ tr(C_i Q P_i Q C_i^T) + λ_N tr(C_i Q C_i^T) < \frac{γ}{N-1}, \]
then the protocol (3) with \( F := -B^T P \) and \( G := QC_i^T \) synchronizes the network (6) and it is suboptimal, i.e. \( J(F, G) < γ \).

Proof. We will only provide the proof for case (i) above. Using the upper and lower bound on \( c \) given by (31), it can be verified that \( c^2 λ_i^3 - 2c λ_N < 0 \). Thus the Riccati inequality (32) has positive definite solutions. Since \( c^2 λ_i^3 - 2c λ_N \leq c^2 λ_i^3 - 2c λ_N < 0 \) and \( λ_i \leq λ_N \) for \( i = 2, 3, \ldots, N \), any positive definite solution \( P \) of (32) also satisfies the \( N - 1 \) Riccati inequalities
\[ A^T P + PA + (c^2 λ_i^3 - 2c λ_N) P B B^T P + λ_N C_2^T C_2 < 0, \]
equivalently,
\[ (A - c λ_i BB^T P)^T P + P (A - c λ_i BB^T P) + c^2 λ_i^3 BB^T P + λ_N C_2^T C_2 < 0, \]
for \( i = 2, \ldots, N \). Using the conditions \( D_1^T C_0 = 0 \) and \( D_1 D_2 = I_m \) this yields
\[ (A - c λ_i BB^T P)^T P + P (A - c λ_i BB^T P) + (c^2 λ_i^3 BB^T P)\]
\[ \times (\sqrt{λ_i} C_2 + λ_i \sqrt{λ_i} D_2 B^T P) < 0, \]
for \( i = 2, \ldots, N \). Taking \( P_i = P \) for \( i = 2, 3, \ldots, N \) and \( F = -B^T P \) in (38) immediately yields (27). Next, it follows from (35) that also (29) holds. By Lemma 4 then, all systems (20) are internally stabilized and \( \sum_{i=2}^{N} J_i(T, F, G) < γ \). Subsequently, it follows from Lemma 3 that the protocol (3) achieves synchronization for the network (6) and \( J(F, G) < γ \).
Remark 6. In Theorem 5, in order to select $\gamma$, the following should be done:

(i) First compute a solution $Q > 0$ of the Riccati inequality (30) and a solution $P > 0$ of the Riccati inequality (32) (or (34), depending on the choice of parameter $c$). Note that these solutions exist.

(ii) Let $S(P, Q) := \text{tr}(C_1 Q P Q C_1^\top) + \lambda_N \text{tr}(Q C_2 Q C_2^\top)$. Obviously, the smaller $S(P, Q)$, the smaller the feasible upper bound $\gamma$. It can be shown that, unfortunately, the problem of minimizing $S(P, Q)$ over all $P, Q > 0$ that satisfy (30) and (32) is a nonconvex optimization problem. However, since smaller $Q$ leads to smaller $\text{tr}(C_1 P Q C_1^\top)$ and smaller $P$ leads to smaller $\text{tr}(C_1 P Q C_1^\top)$ and, consequently, smaller feasible $\gamma$, we could therefore try to find $P$ and $Q$ as small as possible. In fact, one can find $Q = Q(\varepsilon) > 0$ to (30) by solving

$$ AQ + QA^\top - QC_1^\top C_1 Q + E^\top E + \varepsilon I_n = 0. $$

with $\varepsilon > 0$ arbitrary. By using a standard argument, it can be shown that $Q(\varepsilon)$ decreases as $\varepsilon$ decreases, so $\varepsilon$ should be taken close to 0 in order to get small $Q$. Similarly, one can find $P = P(c, \sigma) > 0$ satisfying (32) by solving

$$ A^\top P + P A - P B R(c)^{-1} B^\top P + \lambda_N C_2^\top C_2 + \sigma I_n = 0 $$

with $R(c) = \frac{1}{c^2 + 2c \sigma + \lambda_N} I_n$, where $c$ is chosen as in (31) and $\sigma > 0$ arbitrary. Again, it can be shown that $P(c, \sigma)$ decreases with decreasing $\sigma$ and $c$. Therefore, small $P$ is obtained by choosing $\sigma > 0$ close to 0 and $c = \frac{2}{\lambda_2 + \lambda_N}$. Similarly, if $c$ satisfies (33) corresponding to case (ii), it can be shown that if we choose $\varepsilon > 0$ and $\sigma > 0$ very close to 0 and $c > 0$ very close to $\frac{2}{\lambda_2 + \lambda_N}$, we find small solutions to the Riccati inequalities (30) and (34) in the sense as explained above for case (i).

Remark 7. In Theorem 5, exact knowledge of the largest and the smallest nonzero eigenvalue of the Laplacian matrix is used to compute the local control gains $F$ and $G$. We want to remark that our results can be extended to the case that only lower and upper bounds for these eigenvalues are known. In the literature, algorithms are given to estimate $\lambda_N$ in a distributed way, yielding lower and upper bounds, see e.g. Aragúes et al. (2014). Also, an upper bound for $\lambda_N$ can be obtained in terms of the maximal node degree of the graph, see e.g. Anderson and Morley (1985). Using these lower and upper bounds on the largest and the smallest nonzero eigenvalue of the Laplacian matrix, results similar to Theorem 5 can be formulated, see e.g. Han, Trentelman, Wang, and Shen (2019) or Jiao et al. (2020b).

6. Simulation example

Fig. 1. Plots of the state vector $x^1 = (x_{1,1}, x_{1,2}, \ldots, x_{6,1})^\top$ and $x^2 = (x_{1,2}, x_{2,2}, \ldots, x_{6,2})^\top$ of the controlled network.

In this section, we will give a simulation example to illustrate our design method. Consider a network of $N = 6$ identical agents with dynamics (2), where

$$ A = \begin{pmatrix} -2 & 2 \\ -1 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. $$

$$ E = \begin{pmatrix} 0 & 0 \\ 0.5 & 0 \end{pmatrix}, \quad C_1 = \begin{pmatrix} 1 & 0 \end{pmatrix}, \quad D_1 = \begin{pmatrix} 0 & 1 \end{pmatrix}, \quad C_2 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \quad D_2 = \begin{pmatrix} 1 \end{pmatrix}. $$

The pair $(A, B)$ is stabilizable and the pair $(C_1, A)$ is detectable. We also have $D_1 E^\top = \begin{pmatrix} 0 & 0 \end{pmatrix}$, $D_2 C_1 = \begin{pmatrix} 0 & 0 \end{pmatrix}$ and $D_1 D_1^\top = D_2 D_2^\top = 1$. We assume that the communication among the six agents is represented by the undirected cycle graph. For this graph, the smallest non-zero and largest eigenvalue of the Laplacian are $\lambda_2 = 1$ and $\lambda_6 = 4$. Our goal is to design a distributed dynamic output feedback protocol of the form (3) that synchronizes the controlled network and guarantees the associated cost (10) to satisfy $J(F, G) < \gamma$. Let the desired upper bound for the cost be $\gamma = 17$.

We adopt the design method given in case (i) of Theorem 5. First we compute a positive definite solution $P$ to (32) by solving the Riccati equation

$$ A^\top P + PA - (c^2 \lambda_6^2 - 2c \lambda_6) B B^\top P + \lambda_6 C_2^\top C_2 + \sigma I_2 = 0 $$

with $\sigma = 0.001$. Moreover, we choose $c = \frac{2}{\lambda_2 + \lambda_6} = 0.0952$.

Then, by solving (41) in Matlab, we compute a positive definite solution $P = \begin{pmatrix} 0.9048 & -2.2810 \\ -2.2810 & 6.9779 \end{pmatrix}$. Next, by solving the Riccati equation

$$ AQ + QA^\top - QC_1^\top C_1 Q + E^\top E + \varepsilon I_2 = 0 $$

with $\varepsilon = 0.001$ in Matlab, we compute a positive definite solution $Q = \begin{pmatrix} 0.5000 & 0.5000 \\ 0.5000 & 0.6250 \end{pmatrix}$. Accordingly, we compute the associated gain matrices $F = \begin{pmatrix} 0.2172 & -0.6646 \end{pmatrix}$, $G = \begin{pmatrix} 0.5000 \\ 0.5000 \end{pmatrix}$.

As an example, we take the initial states of the agents to be $x_{10} = (1 - 2)\mathbf{1}$, $x_{20} = (2 - 5)\mathbf{1}$, $x_{30} = (3 \mathbf{1})$, $x_{40} = (4 \mathbf{2})$, $x_{50} = (1 - 2)\mathbf{1}$ and $x_{60} = (-3 \mathbf{1})$, and we take the initial states of the protocol to be zero. In Fig. 1, we have plotted the controlled state trajectories of the agents. It can be seen that the designed protocol indeed synchronizes the network. The plots of the protocol states are shown in Fig. 2. For each i, the state $w_i$ of the local controller is an estimate of the weighted sum of the relative states of agent i, it is seen that the protocol states converge to zero. Moreover, we compute $5 \text{tr}(C_1 Q P Q C_1^\top) + \lambda_6 \text{tr}(Q C_2 Q C_2^\top) = 16.6509$, which is indeed smaller than the desired tolerance $\gamma = 17$.

7. Conclusion and future work

In this paper, we have studied the suboptimal distributed $H_2$ control problem by dynamic output feedback for linear multi-agent systems. The interconnection structure between the agents is given by a connected undirected graph. Given a linear multi-agent system with identical agent dynamics and an associated
global $H_2$ cost functional, we have provided a design method for computing distributed protocols that guarantee the associated cost to be smaller than a given tolerance while synchronizing the controlled network. The local gains are given in terms of solutions of two Riccati inequalities, each of dimension equal to that of the agent dynamics. One of these Riccati inequalities involves the largest and smallest nonzero eigenvalue of the Laplacian matrix of the network graph.

As a possibility for future research, we mention the extension of the results in this paper to the case of heterogeneous multi-agent systems, using, for example, methods from Wieland, Sepulchre, and Allgöwer (2011). It would also be interesting to extend the results in this paper to suboptimal distributed $H_{\infty}$ control by dynamic output feedback.
